Cognitive theories share the basis that one's thoughts and interpretations of the environment are prone to errors, distortions, and incorrect assumptions. Cognitive theories are readily translated into therapeutic interventions, especially through cognitive-behavioral therapy, which seeks to address cognitive distortions and maladaptive assumptions to develop healthier interpretations of, and reactions to events. For example, sex offenders, such as child molesters, tend to have distorted thinking, including what Ward and Keenan (1999) refer to as *implicit theories* about the world, which include viewing children as sexual beings entitled to sexual fulfillment; seeing other adults as dangerous; believing that sexuality is fundamentally uncontrollable; and assuming that there is little harm and potentially even benefits associated with sexually abusing a child. The majority of sex offender treatment programs in the United States and the United Kingdom take a cognitive-behavioral approach in teaching offenders to change their thoughts and behavior patterns in order not to reoffend. These programs are considered empirically supported in reducing recidivism (Beech et al., 2013). Thus, how people think can have a strong impact on their behaviors and how they express their sexuality.

Althof et al. (2005) reviewed how cognitive factors, such as a lack of sexual confidence, anxiety, depression, inadequate sexual information, guilt, and low self-esteem can also trigger or maintain more commonplace sexual problems, such as low sex drive and erectile dysfunction. For example, Barlow (1986) theorized that anxiety in men with erectile dysfunction caused cognitive interference, distractibility, and an inadequate processing of sexual stimuli. Mental distractions from the sexual stimuli are then detrimental to the physical sexual responses of the man. Common cognitive distractions include performance anxiety and feelings of inadequacy. Cognitive-behavioral therapy has also been used to address distorted thinking, anxiety, and maladaptive thoughts in women with hypoactive sexual desire disorder with nearly half the women benefiting from this type of treatment (Althof et al., 2005). Overall, how people think has been implicated in a number of sexual problems and targeting cognitions has become an integral part of sex therapy.

Social Theories

As discussed thus far, theories of sexual behavior can explain sexuality as developing according to biological sex, hormones, genetics, and what has been adaptive in humanity's ancestral past (sociobiology and evolutionary psychology), what is learned through rewards, punishment, and associations between stimuli (operant and classical conditioning), what is observed (social learning theory), and how thought processes can affect sexual functioning (cognitive theories). Thus, these theories are based on the individual and his or her development, biology, learning experience, and cognitions. Although these theories have acknowledged how interacting with the environment is important, the following theories, including the social exchange theory, cultural research, social script theory, and symbolic interactionism emphasize the interpersonal and cultural aspect of sexuality as central to its formation.

The Social Exchange Theory

The social exchange theory has been applied to many different situations; in the context of sexuality, the theory aims at explaining why two particular people may engage in sexual behavior, while another two may not. The theory therefore places the focus predominantly on the relational context. It is placed here under social theories to highlight the strong influence of interpersonal power dynamics, gendered power in society, and because it takes an interpersonal orientation in analysis; however, it is also compatible with evolutionary mate-selection strategies. The social exchange theory posits that human sexuality can be analyzed with the concepts of

economics – that people attempt to maximize their rewards while minimizing costs, that interaction with others is a series of exchanges, and that people who receive rewards feel obligated to reciprocate (Sprecher, 1998).

Within heterosexual culture, the expectation is that men desire sex more than women and thus women have the ability to grant access to something desired. This creates what is referred to as the Principle of Least Interest (Waller and Hill, 1951), which stipulates that the party that has the greater interest in an outcome has less power in negotiations. Thus, women have more power in sexual negotiations and may request additional rewards in exchange, including love, status, money, and influence (Baumeister and Mendoza, 2011). Restricting the availability of sex and increasing its value is therefore of particular importance in cultures where women are disadvantaged in access to income, education, and political representation. Indeed, Baumeister and Mendoza (2011) found that of 37 countries, those which had greater gender equality reported increased casual sexual activity, less abstinence promotion, more premarital sex, and younger age of first intercourse. Thus, as predicted, when women have access to resources through nonsexual means, the 'price' of sexual activity is lower and sex is less restricted.

On an interpersonal level, Byers and Wang (2004) reported that people were more likely to stay in a relationship where they found that the rewards were high and the costs were low. The researchers further noted that partner satisfaction and relationship stability benefited from both partners experiencing a balance of rewards and costs. If one partner felt the other was benefiting more, then for this partner, the temptation to seek rewards outside the relationship increased. This temptation was decreased however, if few or no more appealing alternatives existed (*see* Satisfaction and Commitment in Long-Term Heterosexual Relationships).

The social exchange theory has been criticized on several fronts. One major obstacle in the empirical evaluation of the concept is the subjective nature of costs and rewards, which may differ in value between different people, over time, or through comparisons with other people or rewards. The social exchange model also typically tests how exchanges affect relationships and sexual variables; meanwhile, very little research has been conducted on how the quality of a relationship affects exchange variables. The social exchange theory nevertheless demonstrates that sexual decision-making is grounded in a broader social context that regulates the risks and benefits of sex. It also demonstrates how broad social movements, such as gender equality and feminism, can alter the sexual landscape and affect decision-making.

Social Constructionism

Social constructionism posits that reality is socially constructed, that is, defined and shaped through social interactions, cultural expectations, and language. The degree to which theorists accept objective or biological truths about reality varies widely. Some social constructionists acknowledge that sexuality has an underlying biological drive (i.e., Berger and Luckmann, 1966), while others argue that there is no objective biological essence to sexuality and that it is completely socially defined (i.e., Foucault, 1978). Given that the vast majority of sociological research is social constructionist to some extent, cultural research will first be discussed as an introduction to sociological research, and then, more specifically, script theory and symbolic interactionism will be discussed as particular theories in the field of sociology.

Sociocultural Research

In general, sociological theories examine how social institutions, socialization processes, culture, and language affect sexuality. For example, cross-cultural research demonstrates that women are capable of experiencing sexual pleasure; however, not all cultures recognize the role of pleasure in sexual activity for women. In Uganda, the So people teach women that sex is something to be endured in order to conceive children and no effort is made to encourage sexual pleasure. In contrast, the Mangaian people located in Polynesia are expected from childhood to learn how to give and receive sexual pleasure, and women in this culture are expected to have more orgasms than men and sexual relations before marriage (Allgeier and Allgeier, 1998).

In a cross-cultural study of 190 societies, Ford and Beach (1951) found that attitudes toward homosexuality varied greatly, and thus prevalence also differed. Of 78 less developed societies, the majority (49) approved or tolerated same-sex sexual activity in one form or another. There were other differences, such as whether sexual activity was public (but never in front of children), whether inflicting pain on your partner invokes sexual excitement, or whether masturbation was a regular part of sexuality. Standards of beauty also vary widely from one culture to another, although typically what makes a woman beautiful is more explicitly denoted (*see* Heterosexuality in Africa; Kontula, this work, for discussion of sexuality in Finland; Ng, this work, for discussion of sexuality in China; Richters, this work, for discussion of sexuality in Australia). Alternatively, sexuality has the potential to impact society; as Reiss (1986) argues, even sexually liberal societies place importance on the potential for sexual activity to lead to self-disclosure and pair-bonding. The stability of these interpersonal bonds is important for the formation of families, which are central to societies.

Sociological views of sexuality have been criticized by some theorists who question that social structure or socialization could have any causal role in behavior when compared with the backdrop of sociobiology and evolutionary psychology. Instead, biological drives and tendencies affect culture (Eagly and Wood, 2003). Moreover, sociological theory sometimes focuses on outliers, with cultures that are the exception to the rule taking central place, while the commonalities of the vast majority of cultures may be ignored.

Script Theory

Script theory was pioneered by Simon and Gagnon (1986, 2003) and explored how society defines expectations of sexual behavior. As an attempt to order social behavior, it is important to be able to anticipate the actions of another person. By having predetermined narratives of how sexual

interactions are supposed to occur, people can better predict another person's behavior and act accordingly, making social situations more comfortable.

Sakaluk et al. (2013) conducted a qualitative study on current sexual scripts. They found that dominant heterosexual scripts are typically determined by gender and include assumptions that men are always ready for sex and are the initiators, while women are required to be more reserved, experience less sexual desire, and be the gatekeepers for sex (*see* Femininities). This creates an additional requirement that men are expected to be sexually skilled, knowledgeable, and persuasive, and a lack of skill may be damaging to masculinity (*see* Scripts of Masculinity). However, a new and emerging sexual script for women is emerging that accepts female sexual skills, especially in oral sex. Yet, women are not expected to reveal how they learned these skills to maintain an illusion of inexperience and virginity (Sakaluk et al., 2013). Sexual scripts are also changing the way young adults view relationships and increasingly, noncommitted sexual relationships are becoming the norm rather than exception (*see* Adolescent Sexual Risk). Wentland and Reissing (2011) reported on young adults reliably distinguishing four different casual sexual relationships. These relationships differ in terms of scripts of initiation, maintenance, and termination (Wentland and Reissing, 2012).

Sexual script research has been criticized as lacking predictive power for sexual behavior. Although expectations of behavior are acknowledged, what actually occurs may differ (Bancroft, 2009). Research has yet to determine how sexual scripts affect behaviors such as sexual risk-taking, sexual satisfaction, condom and contraceptive use, and experiencing sexual problems (Sakaluk et al., 2013). On a societal level, sexual scripts are still an important part of determining attitudes toward sexuality, 'appropriate' feelings, and expectations of sexual behavior. They are part of how one learns through socialization, the times and ways in which sexuality is proper and rewarded, as well as when it will be judged as inappropriate (Allgeier and Allgeier, 1998).

Integrated Theories

The previous theories differ widely, ranging in level of analysis from genetic to cultural, but are all derived from data collection and observation. Therefore, which theory is correct? Is sexuality predominantly inborn or shaped through socialization, learning, and culture? Many current theorists acknowledge the empirical basis for multiple theories and choose to integrate different levels of analysis and perspectives in order to create nuanced and comprehensive theories. The following approaches and theories are examples of how these different theoretical lenses can be synthesized into coherent and complex understandings of human sexuality.

The Biopsychosocial Approach

Rather than a predictive theory, the biopsychosocial approach is a paradigm in which biological, social, and psychological aspects of a person are taken into account in order to adequately describe behavior. From this perspective, any clinical intervention for a person with sexual problems should address the biological underpinnings of behavior, the social environment, and the personal psychology of the person (Rossi, 1994; *see* Epidemiology of Sexual Dysfunction). This approach is valuable in that it argues that all levels of analysis are necessary in order to address an issue, from the genetic, hormonal, and evolutionary, to an individual's development, experiences, and cognitions, as well as the interpersonal, social, and cultural aspects of a person's behavior.

A clinician working with a female client with low sexual desire, for example, must investigate whether there are biological reasons such as side effects of prescription medication. Developmental factors may include childhood sexual abuse or a sexually conservative upbringing affecting the experience of the desire for sexual activity. Interpersonal factors may include a lack of communication or comfort in her relationship. If an obstacle exists at any level, then it must be addressed in order to maximize the effectiveness of treatment (Denman, 2004). The biopsychosocial approach is not just clinical in nature; for example, it has been used to analyze sexual behavior such as sexual risk-taking (Bancroft, 2000), how disability affects sexuality (Lindau et al., 2003), HIV/AIDS transmission (Cohen, 1990), and the etiology, maintenance, and treatment of sexual pain disorders (Van Lankveld et al., 2010).

The biopsychosocial approach is difficult to criticize as it considers multiple layers of analyses. It relies on the researcher or clinician to develop ways of integrating theories. In one situation a biological emphasis may be of more use, while in another the psychological perspective may be more appropriate. The approach also does not attempt to distinguish which of multiple psychological theories a researcher should choose from, such as psychoanalytic, cognitive, or behavioral. As a result, there is a risk of atheoretical reasoning and focus on the individual in a predominantly disorder-driven analysis.

The Dual Control Model

The Dual Control Model of Sexuality (DCM; early ref) is an example of a stand-alone theory of sexual motivation that integrates biological mechanisms with psychosocial factors in a very specific, empirically grounded manner (*see* Sexual Motivation). The DCM (Bancroft and Janssen, 2000; see also Bancroft et al., 2009) originates from Gray's (1987) research into Behavioral Activation Systems (BAS) and Behavioral Inhibition Systems (BIS). These two systems help to regulate behavior and motivation through exciting (BAS) and inhibiting (BIS) various responses. The Dual Control Model holds that there is individual variability in thresholds for excitation and inhibition, such that some people are predisposed toward excitation, while others are more predisposed toward inhibition. Bancroft et al. (2009) posit that this variability is usually not problematic unless sexual excitation is particularly high, combined with low inhibition or vice versa. In this case, individuals are at risk for

developing sexual problems such as sexual impulsivity or hypoactive sexual desire.

This model is an integrated theory because it acknowledges both the inherited neurobiology of excitation and inhibition systems in the brain, as well as the effect of cognitions on behavior and the influence of culture. Bancroft and Janssen (2000) developed a questionnaire for excitation and inhibition for men outlining key factors affecting male sexuality: general excitation, inhibitory tone (or general levels of inhibition), and inhibition due to external threats (such as fear of performance failure). Therefore, they argued that men with centrally mediated erectile dysfunction would respond better to psychological therapy if they were prone to inhibition resulting from perceiving threats, whereas those with high inhibitory tone would respond better with pharmaceutical interventions.

As a relatively new theory, more research must be carried out to confirm the initial, promising findings. Although the model was initially constructed using data mostly from men (Rowland, 2006), the development of a DCM questionnaire for women will foster increased research (Graham et al., 2006).

Other Theories to Consider

Despite exploring a range of theories outlining biological, learning, cognitive, social, and integrated theories of sexuality, this list is not exhaustive. For example, political movements resulting in theories such as *Feminist Theory* (e.g., Beasley, 2005) have paved the way to explore how power dynamics and gender roles shape sexuality. Additionally, *Queer Theory* (e.g., Beasley, 2005; Green, 2007) has helped researchers explore how sexual identities are constructed and regulated to produce normative expressions (e.g., heterosexual and monogamous) while discplining and restricting non-normative expressions. Other social constructionist theories include *Symbolic Interactionism* (e.g., Longmore, 1998), which posits that the social world is constructed using symbols; when people interact with the physical world they are constantly interpreting and applying symbolic meanings, which then affect how people relate to themselves and others.

Moreover, this article has not considered the wide variety of theories relating to relationships, the components of love (Sternberg, 1986), and styles of attachment (Feeney and Noller, 1990). The multitude of theories in respect to love, attachment, and relationships are worthy of an entire article of their own.

Conclusion

Despite all the theories, paradigms, and approaches that are available to researchers, modern sexuality research has been criticized for not having a strong theoretical basis (Ainsworth and Baumeister, 2012; Bancroft, 2009; Weis, 2009). As theory guides the formulation and testing of hypotheses, this is problematic. Without theory, many studies are rich in descriptive information, but lack explanatory power. Moreover, information from various sources, however elegantly derived, will need integration to generalize to other individuals, situations, and circumstances to be actually helpful in furthering our understanding of sexuality.

It behooves researchers and theorists to face the challenge of acknowledging empirical support for many different theories and to find a parsimonious explanation to advance sexological science.

Sexually Transmitted Infections: Social Network Analysis

Yoosik Youm, Yonsei University, Seo-dae-moon-ku, Seoul, South Korea

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Since its inception in the mid-1980s, social network analysis has changed the scene of sexually transmitted infection (STI) research in fundamental ways and brought about a paradigm shift. This article surveys the roles of sexual, social, and online networks in STI dynamics. Some challenges for future research are also considered.

In order to identify studies on sexually transmitted infections (STIs) that employed the social network approach, I searched PubMed for papers that contained the term 'social network.' Then, recognizing that there are other terms that are interchangeable with social network, I searched for papers that contained any of the following four terms in the title or abstract: 'social network,' 'social contact,' 'sexual network,' and 'sexual contact.' By reading each abstract, I determined whether the paper was about STIs. This quick survey, which was not comprehensive in any sense, is summarized in Figure 1. From this figure, we can infer three trends. First, there has been a sharp increase in STI studies containing these four terms since the mid-1970s. Second, out of the four related terms, 'sexual contact' appeared first in the early 1970s and continued to be the term most frequently used. Third, the other three terms began to appear in the mid-1980s and continued to grow in frequency except for 'social contact,' which appeared in only a very limited number of papers throughout the period examined. Since 2009, the difference in frequencies between 'sexual contact' and 'sexual network' (or 'social network') has shrunk significantly.

Closer examination of the papers counted in Figure 1, however, puts the picture in a somewhat different perspective. Although papers containing the term 'sexual contact' began to appear very early, the appearance of papers that actually adopted the social network approach did not appear until 1985. Before the social network approach was integrated into STI studies in concrete forms, the term 'sexual contact' was used to mean 'sexual intercourse,' as opposed to other types of interaction or contact leading to STI transmission. For example, In 1985, a case of phthiriasis palpebrarum was examined that was contracted by hand contact as opposed to sexual contact (Dornic, 1985). Another study from that year examined the possibility of acquired immune deficiency syndrome (AIDS) transmission through contacts with household objects without sexual contact (Kaplan et al., 1985).

A Newly Emerged Paradigm: The Social Network Approach

A very early adoption of the social network approach could be found in Rothenberg's study on core group transmission of

Figure 1 The number of STI studies that contained one of the following four terms in the title or abstract: 'sexual network,' 'sexual contact,' 'social network,' and 'social contact.' If a certain paper included more than one term, the paper was counted multiple times.

gonorrhea in the upstate New York area (Rothenberg, 1983). He identified core geographic areas and concentric circles of diminishing incidence in the city. Although he did not explicitly focus on certain social factors above and beyond individual-level risk factors, his results implied that the disease was not universally prevalent but concentrated in specific areas; thus, transmission or contact was by no means random. Instead, sexual contact was selective with regard to race and ethnicity or geographic area, and it must be essential to trace transmission paths (or networks) in addition to individual-level risk factors to understand diffusion dynamics.

In 1985, Potterat and colleagues developed this line of thought to a fuller extent and defined gonorrhea as a 'social disease' (Potterat et al., 1985). After researchers began to model core groups as small sections of the population that are very sexually active and thus responsible for transmission (Hethcote et al., 1982; May, 1981; Yorke et al., 1978), many empirical studies began to prove the existence of such core groups and to recognize that individuals' promiscuity was not sufficient to account for the breakout of STI epidemics (Bell et al., 1985; Fulford et al., 1983; Perine et al., 1985). In addition to individual-level risk factors, Potterat and colleagues realized that the pattern of sexual associations (or sexual networks) between core groups and other population groups must be taken into account; these authors, therefore, "attempted to make social groups the unit of analysis" (Potterat et al., 1985: p. 32).

Also in 1985, Klovdahl explicitly proposed utilizing the social network method to examine the spread of infectious diseases (Klovdahl, 1985). He argued that a basic proposition of social network research is that "the *structure* of a network has consequences for its individual members and for the network as a whole *over and above* effects of characteristics and behavior of the individuals involved" (Klovdahl, 1985: p. 1204, emphasis original). By applying social network methods to data on 40 patients with AIDS, he confirmed that an infectious agent was involved in its spread. He also argued that transmission dynamics are contingent on the structure of the relevant networks. Therefore, he concluded that increasing knowledge of network structures will help us to examine epidemic potential and develop containment strategies.

In the decades following the advent of the social network approach in the mid-1980s, many studies continued to apply this approach to STI dynamics and to focus on the structure of sexual networks (or ties) that exist *between* individuals rather than attributes and behaviors of individuals (e.g., Anderson et al., 1990; Aral and Holmes, 1990; Laumann and Youm, 1999; Morris et al., 1995; Morris and Kretzschmar, 1997; Rothenberg and Potterat, 1988; Rothenberg et al., 1998; Service and Blower, 1995). As Aral observed, this line of study defined a new paradigm for STI research (Aral, 1999). I will examine the role of sexual and social networks in STI transmission from the perspective of this paradigm. At the end of the discussion, I will also discuss some challenges for future research. To begin, I will describe the structural patterns of sexual networks that are known to be essential in the spread of STIs.

Structural Characteristics of Sexual Networks

We can approach sexual networks from several hierarchical perspectives, ranging from individual (or ego) to global. First, the network characteristics of a focal individual may be of interest. For example, the size of the sexual network (the number of sex partners) of a specific individual belongs to this category. Also of potential interest are the characteristics of dyadic sexual relationships such as the age difference or geographical distance between sexual partners. Furthermore, triadic sexual networks are sometimes relevant; these are sexual network patterns that exist among three people or areas. For example, if a certain community keeps a high volume of sexual ties with two other communities that are rarely sexually connected to each other, the first community is of great interest as a potential bridge. Finally, population- or group-level characteristics of a sexual network as a whole are also essential to understanding STI dynamics. For example, we might want to examine the mean or standard deviation of the number of sex partners making up the global sexual network. Ego, dyadic, and triadic network characteristics are often useful for identifying who is at higher risk of infection or who is most responsible for the continuation of STI epidemics or even pandemics. Global network properties could be utilized to determine the distinctive features of STI transmission in a certain population or group. In this section, I describe structural characteristics widely known to be critical in the spread of STIs.

Ego-Level Network Property: Size

Having a large number of sex partners is recognized as one of the most robust risk factors for infection. Numerous studies confirmed that people with multiple partners are more likely to become infected than are people with only one sex partner (Anderson et al., 1994; Ericksen and Trocki, 1992; Joffe et al., 1992; Melnick et al., 1993). The core group, one of the key concepts in early STI models, was itself defined by members' sexual promiscuity (May, 1981; Yorke et al., 1978). Therefore, the number of sex partners of a focal person is very much in line with the traditional approach of clinical medicine, which focuses on individual-level risk factors. In this sense, the number of sex partners of a focal person does not have any effect above and beyond individual behaviors.

Examining the number of partners of a focal person's partners, however, enables us to see STI dynamics in a completely different light. One of the basic propositions of the network approach to studying STIs is that a focal person's probability of becoming infected is dependent not only on his or her own risk factors but also on those of his or her partners. **Figure 2** illustrates this point based on a hypothetical sexual network. Person A and Person B share an identical level of individual risk and the same number of sex partners.

Figure 2 A hypothetical sexual network.

However, both partners of Person A (Person A1 and A2) have three sex partners, while both partners of Person B (Person B1 and B2) have only two sex partners. Other things being equal, Person A is more likely to be infected than Person B not because his or her own level of risk is higher but because his or her partners' level of risk is higher than that of Person B's partners.

Laumann and Youm explained the racial and ethnic differences in the prevalence of STIs in the United States based on this proposition (Laumann and Youm, 1999). They showed that even after controlling for other risk factors, including the number of sex partners, African Americans were about five times more likely to be infected by any bacterial STI than were whites. They proposed that this fact might be attributable to different mixing patterns between African Americans and whites. Using a nationally representative sample, these authors showed that in the African American population, there are many more sexual matches between core partners (having four or more sex partners in the previous year) and peripheral partners (having only one sex partner in the previous year) compared to whites. "For whites, if they are peripheral (instead of being core), they are 180 times more likely to have white peripheral partners (rather than white core partners). However, if they are African American peripherals, they are only 33 times more likely to have African American peripheral partners (rather than African American core partners)" (Laumann and Youm, 1999: p. 255). In other words, there were about six (= 180/33) times more sexual ties between core and peripheral partners within the African American population compared to whites. This means that even if both a peripheral African American and a peripheral white have only one sex partner, the former should have a higher risk of infection because his or her partner is six times more likely to be core.

Dyadic Network Property: Disassortative vs Assortative

One of the most examined questions surrounding STI epidemics is why certain subpopulations or areas have a relatively higher prevalence of infection. As one answer, many studies have singled out the mixing patterns in a sexual network. Other things being equal, disassortative mixing between subgroups eases the spread across the subgroups, while assortative mixing across subgroups contains the diffusion within each subgroup. For example, the relatively high prevalence of STIs among African Americans was explained by disassortative mixing between core and peripheral partners inside the African American population. Furthermore, the prevalence rate within the African American population is kept high due to disassortative mixing between racial and ethnic groups in the United States; African Americans tend to maintain sexual ties only with African Americans rather than with Hispanics or whites (Laumann and Youm, 1999). In a nutshell, STIs spilled over from the core to the entire African American population through disassortative mixing among African Americans, and infections were contained within the African American population because of racial and ethnic disassortative mixing in the United States.

While the previous example employed two dimensions of mixing patterns (racial–ethnic and sexual activity level, i.e., core and peripheral), other dimensions have also proven to be key in understanding STI dynamics. It is widely known that one of the reasons why there was not a more serious AIDS pandemic was the strong disassortative mixing with regard to sexual orientation: the small number of sexual ties between men who have sex with men (MSM) and people of other sexual orientations. In addition to sexual orientation, the dimensions of age and area are of great interest. Age-related disassortative-mixing patterns were confirmed to contribute to larger and faster diffusion of STIs. Younger women, especially adolescents, whose sexual partners were older men reported higher STI incidences in both Africa and the United States (Aral et al., 1999; Darroch et al., 1999; DiClemente et al., 2002; Gregson et al., 2002; Kelly et al., 2003). The effects may reveal a power imbalance in the dyad (or couple), with the older male dominating the sexual negotiation process, tending to lead to more unprotected sex. Conversely, middle-aged women with much younger partners are more frequently diagnosed with STIs in the United States (Kraut-Becher and Aral, 2006). In addition, disassortative mixing with regard to age among MSM seemed to fuel the spread of HIV in the United States. This observation might have resulted from the higher prevalence of HIV among older MSM (Service and Blower, 1996; Morris et al., 1995).

The last mixing pattern to be reviewed is disassortative mixing with regard to area or geographic distance. People who traveled to remote cities and visited sex workers regularly were given special attention because of their potential to spread STIs to geographically distant areas. For example, the behavioral characteristics and STI prevalence of long-distance truck drivers have been examined in Brazil (Lacerda et al., 1997), China (Chen et al., 2006), India (Gawande et al., 2000; Manjunath et al., 2002), Thailand (Morris et al., 1996), and the United States (Valway et al., 2009).

Although disassortative mixing generally makes the spread of STIs easier and faster, there is a tradeoff: In some cases, the number of successive infections decreases, making the diffusion weaker. To take a previous example, frequent sexual relations between core and peripheral partners could hinder transmission if peripheral people who become infected from core partners do not spread STIs further because of their small number of sexual partners. In other words, the basic reproduction rate (the number of people expected to be infected by one person with the STI) must exceed one in order for the STI to continue to exist in a population; disassortative mixing that is sufficiently strong could diminish this rate to below one depending on the transmission parameters, including latent duration, treatment lag, the probability of transmission per sex act, and so on.

Triadic Network Property: Betweenness

Many previous studies have focused on who is more likely to be infected, while only a small number have paid attention to who is more likely to infect other people – the infected vs the transmitter. Without a network approach, the distinction between the two appears meaningless, but the probability of being infected could differ from the power to infect. In **Figure 2**, we concluded that Person A is more likely to be infected than Person B although they have the same number of

sex partners. In order to prevent sexually transmitted disease (STD) transmission, however, protecting Person B might be more important than protecting Person A, as Person B occupies the only path between the two subgroups in the network. In contrast, Person A1 can transmit an STI to Person A2 through Person C without necessarily infecting Person A, thus showing the existence of redundant ties. In this sense, Person B is a much more powerful transmitter than Person A. The important role of bridging people in STI diffusion has been emphasized and empirically confirmed by some studies (Adams et al., 2013; Aral, 2000; Helleringer and Kohler, 2007; Kerani et al., 2003; Nordvik et al., 2007; Youm et al., 2009). For example, Kerani and colleagues confirmed the spatial bridges for gonorrhea and chlamydia infection in the Unites States (Kerani et al., 2003). Using a type of social network analysis called respondent-driven sample (RDS) in a study of drug users in the Chicago area, Youm and colleagues revealed eight *hidden bridging communities*: areas with below-average AIDS prevalence but above-average bridging activities. These communities were largely ignored by public health officials because of their low AIDS prevalence, although their high bridging activities were a key factor in the continuation of the infection in the Chicago area (Youm et al., 2009). The existence, size, and effect of bridging populations are empirical questions. One study showed that in Seattle, the proportion of gonococcal and chlamydial infections attributable to bridge populations was relatively small (Aral et al., 1999).

The challenge in studying bridging activities in STI dynamics is to find an appropriate measure. One of the most widely used network measures for these types of bridging activities is 'betweenness' (Freeman, 1977). The original betweenness score is measured as the frequency with which ego falls between other dyadic nodes (or people) on their shortest paths. An ego that is positioned between other people can facilitate or slow down the transmission; therefore, betweenness is crucial to understanding STI transmission dynamics and to developing effective preventive strategies. The original betweenness measure, however, is not adequate for STI research because it is based on shortest paths that do not allow any repeated points or links. For example, in **Figure 2**, the diffusion process A–A1–C–A2 is not considered when the betweenness score is calculated, given that only the shorter path, A–A2, is taken into account. In addition, reinfection cannot be considered when the betweenness score is calculated because the node (person) cannot appear multiple times in the diffusion process. For example, the diffusion A–A1–A cannot be included despite the fact that multiple infections are possible, except for viral infections to which the host becomes immune. Furthermore, if we change the unit of analysis from the individual to the group or community, multiple infections become the rule rather than the exception: Community A transmits an STI to B, and the STI goes back to community A.

One alternative way to measure bridging activities in STI transmission is to release the assumption of the shortest path. Instead of a *path* that does not allow any repeated nodes or lines, a *walk*, which is an alternating sequence of nodes and lines where an unlimited number of repeated nodes and lines is allowed, was proposed and termed 'walk-betweenness' (Youm, 2010). Walk-betweenness measures the proportion of walks that go through the ego among total walks from the source to the target. Although walk-betweenness is better than path-betweenness for STI research, it is still a universal measure of diffusion rather than one specifically devised for STIs. We need to continue to develop various ways to appropriately measure bridging activities in STI dynamics, incorporating various STI parameters such as transmission probability, infective duration, and latent duration.

Across-Time Network Property: Concurrency

To this point, we have examined the structural characteristics of sexual networks without considering the time dimension. Even when two people have the same number of sex partners, a person who maintains concurrent partnerships plays a different role in the spread of STIs with compared to a person who practices sequential monogamy. The potential role of concurrency was proposed and examined in mathematical models, which showed that concurrent partnerships can dramatically change STI dynamics and increase the number of infected people exponentially (Kretzschmar and Morris, 1996; Morris and Kretzschmar, 1995, 1997). One study also confirmed that sharp racial and ethnic differences in STI prevalence could be partly explained by high rates of concurrent partnerships among African Americans; the authors stated that the observed levels of concurrency and assortative racial mixing would produce a 2.6-fold racial disparity (Morris et al., 2009). Concurrency as a characteristic of a global sexual network in a population appears to fuel the spread of STIs in that population.

Concurrency as a property of individual sexual networks, however, has produced more complicated evidence. Some studies found that people with concurrent partners were more likely to have STI infections. For example, among US adolescents, having a greater number of concurrent partners was associated with STD diagnosis and exposure even after controlling for the number of sex partners (Rosenberg et al., 1999). Another US adolescent study, however, found that teens in sequential or concurrent relationships were more likely to report having an STD than were single-relationship teens (odds ratio (OR) = 2.3 and 3.9, respectively), but they were not statistically different from each other (Kelley et al., 2003). A representative sample of adults from the Chicago area even generated the opposite result; among adults with many lifetime sex partners (13 or more since the age of 18), people who had concurrent partners were less likely to report any STI (OR = 0.35) even after controlling for other risk factors, including the number of lifetime sex partners (Youm and Laumann, 2002). The authors suspected that the answer might lie in the different levels of social embeddedness between concurrency and serial monogamy: "If someone has many sex partners but with no overlap, each partnership is likely to be short and thus casual, approximating one-night stands between strangers with all the risk that entails. In this sense, concurrency may imply longer and thus less risky relationships for people with many sex partners" (Youm and Laumann, 2002: p. 695). This interpretation suggests that future studies may need to measure the duration of each partnership in addition to concurrency.

The Role of Social Networks in STI Transmission

Although Figure 1 shows a consistent increase in the number of publications that included the term 'social network' in the title or abstract since the mid-1980s, many of the counted papers adopted social network analysis and applied it to 'sexual network' data rather than to nonsexual social network data. However, sexual behaviors are among the social acts that contain very deep social meanings and occur under extremely serious social contexts. Thus, in order to understand risky sexual behaviors, it is necessary to examine the social milieux or social networks that produce, reinforce, and change sexual attitudes and behaviors (Bajos, 1997; Delor and Hubert, 2000). Focus group interviews revealed social reasons why certain people in North Carolina engaged in various risky sexual behaviors even when they knew they were dangerous: pervasive economic and racial oppression, lack of community recreation, boredom, and so on (Adimora et al., 2001). In this section, I intend to focus on the role of social (nonsexual) networks in shaping and changing sexual behaviors through factors such as normative pressure, social support, and proper information.

Normative Pressure or Social Support

Depending on the characteristics of members who exert pressure and support, social ties can either encourage or discourage risky sexual behaviors. For example, family members usually will strongly depress risky sexual behaviors. Among black MSM (BMSM), those with a higher family network proportion (having two or more family members in one's close network) were associated with less sex and drug use (OR = 0.38) and less participation in group sex (OR = 0.25) (Schneider et al., 2012). In addition, using a sample of 337 low-income urban African American women with main sexual partnerships, a study concluded that women who had larger nonsexual social networks and more family members in that network were less likely to be in concurrent partnerships (Grieb et al., 2012). Strong control exerted by sexual partners is another factor that strongly restrains unsafe sexual behaviors. One study based on a representative sample in Chicago revealed that among people with a moderate number of lifetime sex partners (1–12), people without strong dyadic (partner) control were more likely to be infected by any STI (Youm and Laumann, 2002).

In contrast to the positive effects of family members or partners on protective sexual behavior, normative pressure from friends could have the opposite effect. One longitudinal study examined how childhood and early adolescent (ages 6–15) peer and nonpeer social networks relate to sexual attitudes and behaviors in adolescence and young adulthood (ages 12–25); it revealed that having a large number of male peers in childhood is related to heightened sexual activity, sexual preoccupation, increased sexual pressure, and risky sexual behavior in adolescence (Noll et al., 2000). Another study used a representative sample of 305 heterosexually active homeless men utilizing meal programs in the Skid Row area of Los Angeles; this study found that the respondents' perception that their social ties (or network alters) engage in risky sex was associated with increased odds of their own concurrency (OR = 3.72) (Wenzel et al., 2012).

Information Provision

In addition to normative pressure and various kinds of social support, social networks are also venues for delivering necessary sexual information in a timely manner (Sprecher and McKinney, 1993). It is not unusual for adolescents to lack proper information about STIs or to underestimate their risk (Mellanby et al., 2000). While adolescents may need information regarding the risk factors of STIs, such as the number of sex partners, condom use, or intravenous (IV) drug use, adults may want information about finding and dealing with potential casual sex partners. A qualitative study on 14 Australian men who acquired HIV while traveling overseas found that social norms and social networks were essential to negotiating sex and social relations in unfamiliar foreign settings (Brown et al., 2012).

People especially rely on informal social networks for concrete information about sexual adventures, such as places where they can find casual but relatively safe sex partners, because "such information is more likely to be available, credible, trustworthy, timely, and specific in such networks" (Youm and Laumann, 2002). This type of information is more needed by people who are very sexually active than by people who have only a moderate number of sex partners.

One study implied that two distinctive advantages of social networks, control and information, could be effective for different subgroups (Youm and Laumann, 2002). Social control may be specifically effective for people with a moderate number of sex partners, given that, in order to avoid STIs, they do not need a constant information feed about potential venues for sexual activities. People with many sex partners, however, may receive protection from information but not from control. People may give up their control over their friends' sexual behaviors once those friends are known to be very sexually active.

Tools for Effective Preventive Programs

Because at-risk people are likely to connect to each other through intimate social networks, the use of such networks could be effective for recruiting, monitoring, and protecting people at potential risk. The US Centers for Disease Control and Prevention (CDC) did a pilot study in which people testing positive or negative (but still at risk) for HIV were required to recruit their social, sexual, and illicit drug partners (network associates (NAs)). They were able to recruit a substantial number of NAs with a high rate of newly diagnosed HIV infection and to do so efficiently (CDC, 2005). In a similar study funded by the CDC, the HIV prevalence of 5.6% among those recruited was significantly higher than the approximately 1% identified in other counseling, testing, and referral sites (Kimbrough et al., 2009).

This recruitment strategy is especially effective for small, hidden populations at high risk, such as MSM or IV drug users who are hard to reach using traditional recruitment methods. BMSM in San Francisco were asked to recruit any of their social contacts who were also BMSM, and 23% of the recruited BMSM

living with HIV were unaware of their infection (Fuqua et al., 2012). This type of snowball sampling was effective for purposes of preventive activities but not ideal for academic research, as the resultant sample should be strongly biased by the characteristics of the seeds who initiated the sampling. We can adjust for this bias to some extent by adopting new sampling procedures developed for social network analysis (Heckathorn, 1997, 2002). Sampling will be discussed in more depth when challenges for future research are presented in this article. For now, let us turn to a newly emerging type of social network: those that are online.

Online Networks as Socially (Un)embedded Places

The sexual-partnering scene has changed dramatically since the advent of the Internet. In particular, various new social networking services (SNSs), where online users are also creators of content, represent an unprecedented phenomenon at the societal level, and relatively little has been discovered about the impact of SNSs on sexual partnering or STI transmission dynamics.

It is intuitive to observe that online partnering leads to more risky behaviors given that many online partnerships are scarcely embedded in one's social surroundings; hence, such partnerships become more similar to sexual encounters between strangers. Many studies have confirmed that a substantial portion of MSM seek sexual partners online, and those who do so are more likely to have an STI history and to engage in high-risk sexual behaviors, including intentional barebacking (sex without condom use) (Benotsch et al., 2002; Elford et al., 2001; Halkitis and Parsons, 2003; Klausner et al., 2000; Liau et al., 2006; McFarlane et al., 2000; Toomey and Rothenberg, 2000).

However, many previous studies ignored the possibility of selection bias; the Internet per se did not increase risky behaviors, but people who relied on the Internet were, from the start, more likely to engage in hazardous behaviors. Some studies have reported the same level of risky behaviors between online and offline partnerships among MSM who looked for sex partners online (Bolding et al., 2005; Chiasson et al., 2007; Hirshfield et al., 2004). Studies on populations outside MSM, meanwhile, produced opposite results. Among men who have sex with women, people who reported Internet partners were less (relative risk = 0.66) likely to have *Chlamydia trachomatis* or *Neisseria gonorrhoeae* infections (Al-Tayyib et al., 2009). Even when the partnering begins online, if much online interaction occurs before the offline meeting and, thus, the partners are tightly embedded into each other's social milieux, the partnership can be safe (Rietmeijer and McFarlane, 2009). Thus, we must avoid making a simple dichotomous distinction between online and offline. Instead, closer examinations of the diverse embeddedness levels of online settings must be emphasized in future research.

Two major characteristics of the online world, relatively high anonymity (or little embeddedness) and the low cost of information diffusion, could represent an opportunity for preventive programs and activities. Online, it is possible to transmit socially stigmatized information, such as advertisements for STI tests, knowledge about STI infections, and partner notification for potential infection, at little cost (for a relatively complete list of online prevention activities, please see Rietmeijer and McFarlane, 2009). More time is needed to judge the effectiveness of online prevention efforts, but some early results do not look promising. Several studies on online STD partner notification programs revealed a degree of effectiveness (e.g., Ehlman et al., 2010) but in a very limited range (Plant et al., 2012; Kerani et al., 2011; Levine et al., 2008; Rietmeijer et al., 2011). One of the most recent studies evaluated InSPOT.org, the first self-contained partner notification website, which was launched in 2005 with funding from the Los Angeles County Department of Public Health Sexually Transmitted Disease Program and AIDS Healthcare Foundation. It was revealed that less than 2% of the respondents who were recruited at a sexual health clinic in Los Angeles had ever sent a notification using the online service (Plant et al., 2012).

The very limited effects of online networking sites on prevention and treatment are not due to there being a small number of visitors to these sites (Rietmeijer, 2012). Rather, it may result from the very nature of online networks: anonymity, low commitment, and low trust. While STI-related information is easily transmitted and advertised quickly and cheaply through online sites, people are not committed to respond unless the information is delivered to the right people at the right time. Unlike offline (social) networks that naturally can provide necessary information in a timely, credible, and specific manner, online networks distribute information in an anonymous, inopportune, and universal manner. A study found that the effectiveness of a syphilis partner notification program, part of the Los Angeles Gay and Lesbian Center's Sexual Program, greatly improved after the placement of community-embedded disease intervention specialists (CEDIS): 15% (21) of 140 partners elicited were identified as having early syphilis and started on treatment, compared to 0% of 13 partners elicited before the placement of CEDIS (Rudy et al., 2012). It is necessary to integrate offline social network support with online networking services for the best preventive outcomes.

Challenges for Future Network Studies

The last several decades have seen a dramatic increase in the use of social network analysis for STIs, beyond a mere increase in the number of studies. This article's discussion of the roles of social network approaches in STI research, although by no means comprehensive, suffices to offer proof of a paradigm shift. Now it has become the rule rather than the exception to take into account the characteristics of sexual partnerships when analyzing STI diffusion dynamics. The primary unit of analysis in STI research has steadily extended outward from individuals to dyadic couples to triadic relationships to global network characteristics. It is certain that future studies of STIs will adopt more elaborate measures, tools, and approaches to conduct social network analysis more fully. In this section, I discuss some challenges for future studies.

There is a need for new analytical tools. First, as discussed in this article, many of the original social network measures were developed for universal purposes, without specific applications

in mind. Some of them, moreover, were specifically designed for economic settings to analyze networks among individuals in firms and industries. The network dynamics involved in STI transmission are quite different from those seen in economic contexts. Thus, direct application of off-the-shelf network measures to STI research should be limited if possible. We are waiting for new measures of centrality, mixing patterns, and bridging activities that are specifically customized for STIs, taking various STI parameters into account. Second, we must adopt new tools to examine the characteristics of global networks. Unlike ego-centric sexual networks, global sexual networks cannot guarantee the independence assumption that is required for statistical analysis, as ties are not independent of each other. Social network analysis has seen a continuous improvement of stochastic models in terms of relaxing the independence assumption in various forms. Various types of exponential random graph models were advanced, the most recent being the development of the Markov chain Monte Carlo maximum likelihood estimation (MCMCMLE) for the model (Robins et al., 2007; Snijders et al., 2006; Wang et al., 2013; Wasserman and Pattison, 1996). We must stay attentive to the development of tools to analyze global networks.

Another hurdle is posed by the need to identify a proper sampling scheme. Many studies still adopt nonrepresentative sampling to collect sexual (social or drug) network data such as contact tracing, targeted sampling, or time venue sampling. The resultant network data usually have a strong bias toward people at high risk, reducing their suitability for rigorous scientific study (Laumann and Youm, 1999). Two alternatives are presently possible. First, we can conduct representative sampling of the general population. Examples include the National Health and Social Life Survey (Laumann and Youm, 1999), the National Survey of Family Growth (Kraut-Becher and Aral, 2006), the National Health and Nutrition Examination Survey (Allsworth et al., 2009), and the National Longitudinal Study of Adolescent Health (Pflieger et al., 2013). Representative sampling, however, requires a substantially larger investment of time and money. Furthermore, it is not suited for studying small, hard-to-reach populations such as MSM or IV drug users; from the start of sampling, it is quite hard to identify people who belong to such small and hidden populations. For such populations, snowball sampling has been widely used, but as in other forms of nonrepresentative sampling, the final sample usually has a large bias toward the seeds, or the respondents initiating the snowballing.

Fortunately, RDS was proposed to adjust for the biases of snowball sampling (Heckathorn, 1997, 2002) and has been adopted by many STI studies (Jenness et al., 2011; Johnson et al., 2009; Mimiaga et al., 2007; Neaigus et al., 2013; Youm et al., 2009). Although RDS provides statistical estimates and variances, whether the assumptions for the inference can be met in practice is not certain (Lansky et al., 2012; McCreesh et al., 2012; Rudolph et al., 2011, 2013). However, other types of applications such as risk factor identification, efficient network data collection, and population size estimation are also possible, and these applications require fewer (or no) sampling assumptions (White et al., 2012).

Another data-related issue is the integration of biomarkers. Given the strong social stigma attached to STIs and the high proportion of asymptomatic STI cases, self-reported STI status tends to be underestimated, and biomarkers from physical examination for STIs are helpful for more accurate estimation of respondents' STI status (Kraut-Becher and Aral, 2006). In addition, data on sexual networks from surveys are inevitably incomplete and egocentric: respondents tend to omit information about some of their sexual partners. Furthermore, we usually do not and cannot interview all of the sex partners of respondents. Under the assumption that individuals infected by the same strain of an infectious agent are more likely to have a sexual link, molecular typing can produce a sexual network: a biomarker-produced sexual network (Day et al., 1998; Hesse et al., 1995; Ota et al., 2011; Wylie et al., 2005). Given that many health-related survey studies have begun to accommodate biomarkers in their data sets, we can expect to see more STI data sets where network surveys are combined with biomarkers. There is a need to identify tools to build a more complete and accurate sexual network by combining a survey-based sexual network with a biomarker-produced sexual network.

Abstract

In this article the main focus lies on the shadow economy labor force in OECD, developing, and transition countries. Besides informal employment in the rural and nonrural sector also other measures of informal employment like the share of women and men are shown. The most influential factors on the shadow economy labor force are tax policies and state regulation, which, if they rise, increase both. Furthermore, the discussion of the recent microstudies underlines that economic opportunities, the overall burden of the state (taxes and regulations), the general situation on the labor market, and unemployment are especially crucial for an understanding of the dynamics the shadow labor force.

Introduction

Fighting informal (illegal) or shadow employment has been an important policy goal in most countries during recent decades. In order to do this one should have knowledge about the size and development of shadow economy labor force as well as the reasons why people are engaged in shadow economy activities. In this mostly empirically orientated article I am mainly concerned with the size and development of black activities or undeclared work, and the shadow economy labor force.

This article is organized as follows: Section Some Theoretical Considerations about the Shadow Economy Labor Force and Labor Market presents theoretical considerations about the shadow economy labor force and labor market. In Section Shadow Economy Labor Force – Empirical Results a discussion of the size and development of the shadow economy labor force and its various aspects is undertaken. In Section Shadow Economy and Unemployment the interaction between the shadow economy and unemployment is analyzed. Finally Section Conclusions concludes.

Some Theoretical Considerations about the Shadow Economy Labor Force and Labor Market

Having examined the size, rise and fall of the shadow economy in terms of value added over time, the analysis now focuses on the 'shadow labor market,' as within the official labor market there is a particularly tight relationship and 'social network' between people who are active in the shadow economy. (Pioneering work in this area has been done by L. Frey (1972, 1975, 1978, 1980), Jöreskog and Goldberger (1975), Cappiello (1986), Lubell (1991), Pozo (1996) and Tanzi (1999). One of the latest surveys or background paper is Hazans (2011) dealing with informal workers across Europe.) Moreover, by definition every activity in the shadow economy involves a 'shadow labor market' to some extent: (Compare also one of the latest OECD reports with the title *Is Informal Normal: Toward More and Better Jobs* by the OECD (2009).) Hence, the 'shadow labor market' includes all cases, where the employees or the employers, or both, occupy a 'shadow economy position.'

Why do people work in the shadow economy? In the official labor market, the costs firms (and individuals) have to pay when 'officially' hiring someone are tremendously increased by the burden of tax and social contributions on wages, as well as by the legal administrative regulation to control economic activity. In various OECD countries, these costs are greater than the wage effectively earned by the worker – providing a strong incentive to work in the shadow economy.

More detailed theoretical information on the labor supply decision in the underground economy is given by Lemieux et al. (1994) who use microdata from a survey conducted in Quebec City (Canada). (Compare also the microstudy of the shadow labor market for Germany by Haigner et al. (2013).) In particular, their study provides some economic insights regarding the size of the distortion caused by income taxation and the welfare system. The results of this study suggest that hours worked in the shadow economy are quite responsive to changes in the net wage in the regular (official) sector. Their empirical results attribute this to a (mis-) allocation of work from the official to the informal sector, where it is not taxed. In this case, the substitution between labor market activities in the two sectors is quite high. These empirical findings indicate, that "participation rates and hours worked in the underground sector also tend to be inversely related to the number of hours worked in the regular sector" (Lemieux et al., 1994: p. 235). These findings demonstrate a large negative elasticity of hours worked in the shadow economy with respect both to the wage rate in the regular sector as well as to a high mobility between the sectors.

Illicit work can take many forms. The underground use of labor may consist of a second job after (or even during) regular working hours. A second form is shadow economy work by individuals who do not participate in the official labor market. A third component is the employment of people (e.g., clandestine or illegal immigrants), who are not allowed to work in the official economy. Empirical research on the shadow economy labor market is even more difficult than that of the shadow economy on the value added, since one has very little knowledge about how many hours an average 'shadow economy worker' is actually working (from full time to a few hours, only); hence, it is not easy to provide empirical facts (For developing countries some literature about the shadow labor market exists; compare Dallago (1990), Pozo (1996), Loayza (1996), Chickering and Salahdine (1991), and OECD (2009).).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.94036-4

Kucera and Roncolato (2008: p. 321) also deal with informal employment. They address two issues of crucial importance to labor market policy:

1. The intensive labor market regulations as one (major) cause of informal employment, and
2. the so-called 'voluntary' informal employment. Kucera and Roncolato give a theoretical overview on both issues and also a survey of a number of empirical studies, in which mainly the effect of official labor market regulations on informal employment is analyzed, where they find a significant and quantitatively important influence.

Shadow Economy Labor Force – Empirical Results

Worldwide Aspects – Latest Results

The following results of the shadow economy labor force are based on the OECD and World Bank database on informal employment in major cities and in rural areas, as well as on other sources mentioned in the footnotes of this article and the tables. The values of the shadow economy labor force are calculated in absolute terms, and as a percentage of the official labor force, under the assumption that the shadow economy in rural areas is at least as high as in the cities. This is a conservative assumption, since in reality it is likely to be even larger. (The assumption that the shadow economy labor force is at least as high in rural areas as in major cities, is a very modest one and is supported by Lubell (1991). Some authors (e.g., Lubell (1991), Pozo (1996), and Chickering and Salahdine (1991)) argue that the illicit labor force is nearly twice as high in the countryside as in urban areas. But since no (precise) data exists on this ratio, the assumption of an equal size may be justified arguing that such a calculation provides at least minimal figures.) Survey techniques and, for some countries, the MIMIC method, and the method of the discrepancy between the official and actual labor force are used for estimation.

One of the latest studies is the OECD (2009) (see also OECD (2008)) one with the title *Is Informal Normal?*, which provides worldwide figures. This OECD study (the following results and figures are taken from the OECD (2009), executive summary) concludes that in many parts of the world and over the period 1990–2007 informal employment is the norm, not the exception. More than half of all jobs in the nonagricultural sectors of developing countries – over 900 million workers – can be considered informal. If agricultural workers in developing countries are included, the estimates size to roughly 2000 million people. In some regions, including sub-Saharan Africa and South Asia, over 80% of nonagricultural jobs are informal. Most informal workers in the developing world are self-employed and work independently, or owe and manage very small enterprises. According to the OECD study (2009), informal employment is a result of both, people being excluded from official jobs and people voluntarily opting out of formal structures, e.g., in many middle-income countries incentives drive individuals and businesses out of the formal sector.

To summarize, this OECD study clearly comes to the conclusion that informal is really the norm or the normal case. There are 1800 million people working in informal jobs, compared to 1200 million who benefit from formal contracts and social security protection. Informal economic activity, excluding the agricultural sector, accounts for three-fourth of the jobs in sub-Saharan Africa, more than two-thirds in South and Southeast Asia, half in Latin America, the Middle East, and North Africa, and nearly one-fourth in transition countries. If agriculture is included, the informal share of the economy in the above mentioned regions is even higher (e.g., more than 90% in South Asia). Also, this OECD study comes to the result that more than 700 million informal workers 'survive' on less than $ 1.25 a day and some 1200 million on less than $ 2 a day. The study also concludes that the share of informal employment tends to increase during economic turmoil. For example, during the Argentine economic crisis (1999–2002), the countries' 'official' economy shrank as by almost one-fifth while the share of informal employment expanded from 48 to 52%. One can clearly conclude that even under strong economic growth, the share of nonagricultural employment and informal employment is strongly rising.

OECD Countries

In Table 1 the estimates for the shadow economy labor force in highly developed OECD countries (Austria, Denmark, France, Germany, Italy, Spain, and Sweden) are shown. (Shadow economy labor force consists of estimated full-time 'black' jobs, including unregistered workers, illegal immigrants, and second 'black' jobs.) In Austria the shadow economy labor force has arrived at 500 000–750 000 or 16% of the official labor force (mean value) in the years 1997–98. In Denmark the development of the 1980s and 1990s shows that the part of the Danish population engaged in the shadow economy ranged from 8.3% of the total labor force (in 1980) to 15.4% in 1994 – quite a remarkable increase of the shadow economy labor force; it almost doubled over 15 years. In France (in the years 1997/98) the shadow economy labor force reached a size of between 6 and 12% of the official labor force or between 1.6 and 3.2 million in absolute figures. In Germany this figure rose from 8 to 12% in 1974 to 19 and 22% (8 millions) in 1997/98, respectively. For France and Germany this is again a very strong increase in the shadow economy labor force. In other countries the amount of the shadow economy labor force is quite large, too: in Italy 30–48% (1997–98), Spain 11.5–32% (1997–98), and Sweden 19.8% (1997–98). In the European Union about 30 million people are engaged in shadow economy activities in 1997–98 and in all European OECD countries 48 million people work illicitly.

These figures demonstrate that the shadow economy labor market is lively and may provide an explanation, why, for example, in Germany, one could observe such a high and persistent unemployment up to the year 2007.

Additionally, Table 1 contains a preliminary calculation of the total GDP per capita (including the official and the shadow economy GDP per capita) in US-$. In all countries investigated, total GDP per capita is much higher – on average in all countries around 40%. This clearly shows that the productivity in the shadow economy is roughly as high as in

the official economy – a clear indication, that the work effort (i.e., the incentive to work effectively) is as strong in the shadow economy as in the official one. In general these results demonstrate that the shadow economy labor force has reached a remarkable size in the developing countries as well as in highly developed OECD countries, even though the calculation still might have many errors.

Developing and Transition Countries

There have been some newer studies with respect to estimate the size and development of the shadow economy labor force (see also Schneider (2005, 2011), Schneider and Enste (2000), Feld and Schneider (2010), Schneider et al. (2010), Williams and Windebank (2001a,b), Williams (2010a,b, 2011a,b), and Hazans (2011).). Kucera and Roncolato (2008: p. 321) deal with informal employment. They address issues of crucial importance to labor market policy; first, the intensive labor market regulation is one major cause of informal employment, and second, the so-called voluntary informal employment. Kucera and Roncolato give a theoretical overview on both issues and also a survey of a number of empirical studies, in which the effect of the official labor market regulations on informal employment is analyzed, where they find a significant and quantitatively important influence.

In **Table 2** the share of informal employment in total nonagricultural employment by 5-year period and by region is presented. From the table one clearly sees that in all regions the share of informal employment has remarkably increased over time. The share of informal employment in South- and Middle-American countries in the period of 1985–89 was 32.4% and increased in the period of 2000–07 to 50.1%. In 34 Asian countries informal employment rose in the period of 1985–89 from 55.9 to 70.2% from 2000 to 2007. In the 42 African countries the share of informal employment (in percent of total nonagricultural employment) was 40.3% from 1985 to 1989, and increased to 60.5% in 2000–07. **Table 2** clearly demonstrates that there is a very strong positive trend in the share of informal employment (in percent of total nonagricultural employment).

Table 3 provides the share of informal employment in total nonagricultural employment by country, region, and gender. If one splits up the share of informal employment (in percent of total nonagricultural employment) by gender, I generally observe, that the share of women is significantly higher than the share of men. In North Africa (countries Algeria, Morocco, Tunisia, Egypt) the share of informal employment of women is 43.3% and the one of men 49.3% over the period 1990–99. In sub-Saharan Africa the share of women is 84.1%, the one of men 63.0%. In Latin America the share of women is 56.2% and the share of men 47.1%. Only in the region of West Asia and in the transition countries the share of men of informal employment is higher than the one of women. In West Asia (countries Lebanon, West Bank and Gaza Strip, Syria, Turkey, Yemen) the share of women is 31.1%, the share of men 43.4%. In the Transition countries (Kyrgyzstan, Moldova,

OECD and World Bank, Washington and Paris.

Russia) the share of women is 22.3% and the share of men 27.2%. I also realize some remarkable differences. In general the share of informal employment is rather large worldwide and certainly has severe policy implications.

Shadow Economy and Unemployment

(This part is taken from Feld and Schneider (2010).) Although there has been some discussion on the size of the shadow economy labor force and on its reasons, comparatively little attention has been given to the relationship between unemployment and working in the shadow economy. As Tanzi (1999) points out, "the current literature does not cast much light on these relationships even though the existence of large underground activities would imply that one should look more deeply at what is happening in the labor market" (p. 347). The objective of the article by Bajada and Schneider (2009) is to examine the extent of participation in the shadow economy by the unemployed. Their paper has investigated the relationship between the unemployment rate and the shadow economy. Previous literature on this topic has suggested that the relationship between these two variables is ambiguous, predominantly because a heterogeneous group of people working in the shadow economy exists and there are also various cyclical forces at work, such that they produce a net effect that is weakly correlated with unemployment. In their paper they have provided a suggestion for disentangling these cyclical effects, so as to study the component of the shadow economy that is influenced directly by those who are unemployed. They refer to this effect as the 'substitution effect,' which typically increases during declining periods of legitimate economic activity (and increasing unemployment). Equipped with this approach for measuring the 'substitution effect,' they discover that a relationship exists between changes in the unemployment rate and shadow economy activity.

By examining the growth cycle characteristics of the 'substitution effect' component of the shadow economy Bajada and Schneider (2009) determine that the growth cycles are

symmetric (in terms of steepness and deepness) and that changes in the unemployment rate, whether positive or negative, had similar impacts on changes in the substitution effect component. They suggest that the shadow economy is a source of financial support during periods of unemployment for those genuinely wanting to participate in the legitimate economy. Although this does not exclude the possibility that long-term unemployed may also be participating in the shadow economy, it would appear that short-term fluctuations in unemployment directly contribute to short-term fluctuations in the shadow economy.

When Bajada and Schneider consider the various unemployment support programs across 12 OECD countries, there appears to be no real systematic relationship between the generosity of the social security systems and the nature of short-term shadow economic activity by the unemployed. Even the various replacement rates across the OECD countries appear to have little consequence on the rate at which the unemployed take on and cut back shadow economy activity. There is however some evidence to suggest that extended duration spell in unemployment lasts anywhere between less than 3 months to approximately 9 months.

On the whole Bajada and Schneider argue that dealing with unemployment participation in the shadow economy as a way of correcting the inequity it generates, is best handled by more stringent monitoring of those receiving unemployment benefits rather than reducing replacement rates as a way of encouraging reintegration into the work force. A strategy of reducing replacement rates would not only fail to maintain adequate support for those experiencing financial hardship during periods of unemployment, it is likely to have little impact on reducing participation by the unemployed who are willing and able to engage in shadow economy activity.

Conclusions

In this article some of the most recent developments in research on the shadow economy labor force and undeclared work in highly developed OECD, developing, and transition countries are shown.

The discussion of the recent literature shows that economic opportunities for employees, the overall situation on the labor market, not least unemployment are crucial for an understanding of the dynamics of the shadow economy. Individuals look for ways to improve their economic situation and thus contribute productively to aggregate income of a country. This holds regardless of their being active in the official or the unofficial economy.

If I come back to the headline of this article "Work in the shadow: Some Facts" I clearly realize that we have some knowledge about the size and development of the shadow economy labor force. For developing and transition countries, the shadow economy labor force has reached a remarkable size according to OECD (2009) estimates, which is, that in most developing countries the shadow economy labor force is higher than the official labor force. What we do not know are the exact motives, why people work in the shadow economy and what is their relation and feeling if a government undertakes reforms in order to bring them back into the official economy. Hence, much more microstudies are needed to obtain a more detailed knowledge about people's motivation to work either the shadow economy and/or in the official one.

Shamanism

Donald Joralemon, Smith College, Northampton, MA, USA

This article is reproduced from the previous edition, volume 21, pp. 14032–14035, © 2001, Elsevier Ltd.

Abstract

Shamanism is a tradition of part-time religious specialists who establish and maintain personalistic relations with specific spirit beings through the use of controlled and culturally scripted altered states of consciousness (ASC). Shamans employ powers derived from spirits to heal sickness, to guide the dead to their final destinations, to influence animals, and forces of nature in a way that benefits their communities, to initiate assaults on enemies, and to protect their own communities from external aggression. The following paragraphs cover common features of shamanic traditions, techniques for inducing ASC, and popular versus academic uses of the term (e.g., in New Age religions, in symbolic anthropology). The article ends with a quick review of 'dead ends and detours' in shamanism studies, including speculations about shamans' mental status and the place of shamanism in cultural evolution. It calls for a refocusing of the term to a more restricted definition.

Shamanism is a tradition of part-time religious specialists who establish and maintain personalistic relations with specific spirit beings through the use of controlled and culturally scripted altered states of consciousness (ASC). Shamans employ powers derived from spirits to heal sickness, to guide the dead to their final destinations, to influence animals and forces of nature in a way that benefits their communities, to initiate assaults on enemies, and to protect their own communities from external aggression.

Shamans exercise mastery over ASC and use them as a means to the culturally approved end of mediating between human, animal, and supernatural worlds. Shamans draw pon background knowledge, conveyed through myth and ritual, which renders intelligible the potentially chaotic experience of ASC. The criterion of control helps to distinguish shamanism from the use of ASC in other traditions.

Shamanism has long been a subject of inquiry and controversy in diverse academic disciplines, with many hundreds of accounts of shamanic practices published by the early 1900s. It has also been a topic of spiritual interest to the wider public in Europe and North America for the past several decades. Depending on the perspective taken, shamanism is either the most archaic and universal form of human spirituality or a culturally distinct religious complex with historical roots in Siberia and a path of diffusion into North and South America. The latter view is adopted in the following.

Siberian Origin and Common Features

The term 'shaman' is drawn from seventeenth century Russian sources reporting on an eastern Siberian people, the Evenk (Tungus). In the classic work on the subject by the historian of religion Mircea Eliade, 'shamanism' is used to refer to a complex of beliefs and practices diffused from northern Asia to societies in central and eastern Asia, as well as through all of North and South America. Eliade's comparative work specifies a core constellation of ideas common to shamanic traditions. The classic shamanic initiation involves the novice's selection – frequently unwanted and resisted – by a spirit(s), a traumatic and dangerous series of ordeals, followed by a death and rebirth that sometimes involves violent dismembering and subsequent reconstitution of the fledgling shaman's body. The archetypal shamanic cosmology is vertically tiered, with earth occupying the middle level and a cosmic tree or world mountain serving as a connecting path for shamans to travel to other cosmic planes (up or down) in pursuit of their 'helping spirits.'

Shamans use a variety of techniques to enter the ASC in which they communicate with their spirit helpers: sensory deprivation (e.g., fasting, meditation), repetitive drumming and/or dancing, and ingestion of substances with psychoactive properties (e.g., plant hallucinogens). The last of these means is particularly important in the shamanism of Central and South America, where an impressive array of plants and animal-derived chemicals have been used for their hallucinogenic properties (e.g., peyote, datura, virola, and poison from the *Bufo marinus* toad).

Among the most commonly reported characteristics of the shaman's ASC are transformations into animals, and flights to distant places. Shamanic animals include the jaguar (lowland South America), the wolf (North American Chukchee), and bears, reindeer and fish (Lapp). Shamanic flights are undertaken to recapture the wandering souls of the sick, to intercede on behalf of hunters with spirits that control animal species, and to guide the dead to their final destination.

The fact that shamans are often called upon to heal the sick should not lead to the conclusion that they are always concerned with the well being of their fellows. While the Hippocratic Oath of Western medicine prohibits physicians from doing harm, shamans frequently engage in actions meant to sicken, if not kill, their adversaries. This is an important corrective to romanticized images of the shamanic vocation.

Popular and Professional 'Shamanism'

Beginning in the 1960s there developed a convergence in the professional and popular interests in shamanism. Inspired by the experimentation with hallucinogenic drugs on the part of American and European youth, attention was drawn to the physiology and psychology of altered states of consciousness.

In academic circles, this led to speculations about the neurochemical foundations of hallucinatory experiences and their potential therapeutic benefits. Investigations were undertaken into the imagery of shamanic states of consciousness to determine how much could be attributed to universal, physiologically related sensory experiences. One often cited collection of essays, published in the journal *Ethos* (Prince, 1982), sought to link the shaman's ASC to the production of the naturally occurring opiates known as endorphins. Scholars argued that this might account for the healing effect of shamanic therapies.

In the popular cultures of North America and Europe, stress came to be placed on shamanism as an avenue to self-exploration, a means by which persons from any culture could advance their quest for spiritual understandings. The legacy of this development is to be found in the forms of 'neoshamanism' among New Age religions, which draw eclectically from more traditional shamanic practices. Native North and South American societies have been special sources of inspiration for practitioners of neoshamanism, but not always with the willing support of the indigenous people.

At the same time, and in response to the evolution of research in symbolic anthropology, anthropologists have contributed increasingly sophisticated ethnographic analyzes of the metaphysical underpinnings of shamanism in specific societies. These anthropologists concentrate their attention on the complexities of shamanic cosmologies and the relationships between shamanic symbolism and crucial features of the natural world (e.g., important animal and plant species, meteorological phenomena, and geographic landmarks).

An especially detailed analysis of a shamanic tradition comes from the Warao of the Orinoco Delta in Venezuela. The German-born and American-trained anthropologist Johannes Wilbert documents the mythic cosmology that supports the work of three distinct kinds of shamans, each of which are responsible for the care and feeding of specific gods. The highest ranking shaman, the Wishiratu ('Master of Pains' or Priest Shaman), responds when the Kanobos (Supreme Beings) send sickness to a Warao village. The Bahanarotu is also a curer, but has a special responsibility for a fertility cult centered on an astonishingly complex supernatural location, the House of Tobacco Smoke, where four insect couples and a blind snake play a game of chance under the watchful eye of a swallow-tailed kite. The Hoarotu (Dark Shaman) has the unpleasant but essential task of feeding human flesh to the Scarlet Macaw, the God of the West. The preferred food of the other gods is tobacco smoke, which is also the vehicle by which Warao shamans enter ASC – by hyperventilating on long cigars made of a strong black leaf tobacco.

Research Directions

Dead Ends and Detours

There have been a number of dead ends and detours in shamanism studies. An unfortunate amount of energy was spent in fruitless discussions of the mental health of shamans – whether or not their abnormal behavior justified the application of psychiatric diagnoses (e.g., schizophrenia). Most scholars now recognize that the culturally patterned nature of shamans' behavior and the positive value placed on their social role make the application of mental illness labels inappropriate.

Another distraction came when cultural evolutionists hypothesized that shamanism was an intermediary stage in the developmental sequence of religious forms, in-between magic and institutionalized religion. Attempts to treat shamanism exclusively as an archaic expression of human religiosity flounder on the perseverance and even revitalization of shamanic traditions in cultures around the world. For example, the remarkable resiliency of shamanic practices is evident in the continuity between contemporary *curanderismo* (curing) on Peru's north coast and shamanic iconography dating to the pre-Hispanic Chavin culture (*c.*900–200 BC).

Positive Directions

A still limited amount of research has been directed toward the important question of how effective are shamanic treatments. This work has been troubled by serious theoretical issues (e.g., what constitutes 'efficacy') and thorny methodological questions (e.g., is the double blind, randomized trial possible under the unusual circumstances of shamanic rituals?). The previously cited endorphin theory has not been confirmed ethnographically. Another approach has adapted psychiatric questionnaires to before and after treatment interviews with shamanic patients.

A fruitful line of investigation has focused on the relationship between shamanism and culturally constructed notions ofgender. Shamans sometimes 'bend' gender roles (e.g., transvestitism) and the sicknesses they treat can be entangled in gender-based conflicts. Some scholars suggest that where women dominate in the shaman role there is a less adversarial model of supernatural mediation than with male shamans. The best examples of gender-focused research come from East Asia (especially Korea), where the majority of shamans are women, and from the Chilean Mapuche, among whom female and cross-dressing male shamans have predominated since at least the sixteenth century.

A final body of research worth noting focuses on the capacity of shamanic traditions to survive and thrive even under the most disruptive social and political conditions. Agents of culture change, whether they are Soviet-era ideologues in Siberia or Christian missionaries in the Amazon, have been repeatedly frustrated in their attempts to obliterate shamanic practices. In recent decades, shamans have even become central figures in the politics of ethnicity and in anti-development protests. Scholars have shown that shamans accomplish this survival feat not by replicating ancient traditions, but by continuously reinventing them in the light of new realities and competing symbolic structures. While this strategy may occasion debates about what constitutes an 'authentic' shaman, it is nevertheless the key to shamanism's continuing success.

A Plea for Terminological Precision

The most serious threat to the academic study of shamanism lies in the broad application of the term to any religiously inspired trance form. To so dilute the concept as to make it

applicable to Kung trance dancers, New Age spiritualists, and Mexican Huichol peyote pilgrims is to render it meaningless. The value of a scientific term is that it groups together phenomena that are alike in significant regards, while distinguishing those that are different. The promiscuous use of the term shaman will ultimately leave it as generic as 'spiritual healer,' and just as devoid of analytic value.

Shame and the Social Bond

Thomas Scheff, UCSB, Santa Barbara, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article proposes that shame may be the hidden key to understanding our civilization, in the sense that shame or its anticipation is virtually ubiquitous, yet, at the same time, usually invisible. C.H. Cooley's idea of the looking glass self implies that shame and pride can be seen as signals of the state of the social bond. Theoretical work by Cooley and Erving Goffman imply ubiquity, and empirical studies by Norbert Elias and Helen Lewis provide support. The findings of Elias and Lewis also suggest that shame is usually invisible; Elias stated this proposition explicitly. Like other emotions, such as fear, shame can be recursive, acting back on itself (shame about shame). In unusual circumstances, limitless recursion of shame may explain extreme cases of silence or violence.

The psychologist Gershen Kaufman is one of several writers who have argued that shame is taboo in our society:

> American society is a shame-based culture, but shame remains hidden. Since there is shame about shame, it remains under taboo. …The taboo on shame is so strict that we behave as if shame does not exist (Kaufman, 1989).

Kaufman's phrase, shame about shame, turns out to have meaning beyond what he intended: just as fear can lead to more fear, causing panic, shame about shame can loop back on itself to various degrees, even to the point of having no natural limit. Recursion of shame will be discussed further below (for a discussion of the recursion of thought, see Corballis, 2007). Suppose that shame is usually hidden, as suggested by the idea of taboo. What difference would it make? Before taking up this issue, it will first be necessary to understand what is meant by the term shame.

Definitions of Shame

A linguistic way of hiding shame would be to misname all but the most intense or obvious occurrences. The word shame is defined very narrowly in English: an intense crisis response to inadequacy or misbehavior. In English also, unlike most other languages, shame is kept distinct from less intense siblings, notably, from embarrassment. Other languages treat shame as a family of feelings that extends into everyday life. In Spanish, for example, the same word, *verguenza*, is used to mean both shame and embarrassment, and in French, the term *pudeur*, which is translated into English as modesty, is considered a part of the shame family.

There is a social definition of shame in maverick psychoanalysis and in sociology that defines shame broadly, in a way that includes both embarrassment and guilt, and many other shame variants. Erikson (1950) rejected Freud's assumption that guilt was the primary moral emotion for adults. He argued instead that shame was more elemental in that it concerned the whole self, not just one's actions.

This idea was expanded by the sociologist Helen Lynd, who outlined the crucial importance of shame in the constitution of the self and in social life. She was the first to recognize the need for a *concept* of shame that would be clearly defined in order to avoid the misconceptions of vernacular usage.

The next step was taken by the psychologist Silvan Tomkins, who proposed that shame plays a central role in behavior. In his volume on the 'negative affects' (1963, vol. II), he devoted almost *500 pages* to a detailed discussion of shame and humiliation. This treatment dwarfs his discussion of the other emotions. His examples of shame imply a broad conception. Indeed, he argued explicitly that embarrassment, shame, and guilt should be recognized as members of a single affect family, as I do here. How does this family enter into the daily life of modern societies?

The Looking Glass Self

In his first and most general book, Erving Goffman made a surprising claim:

> There is no interaction in which participants do not take an appreciable chance of being slightly embarrassed or a slight chance of being deeply humiliated (1959, p. 243).

This statement occurs only in passing toward the end of the book. Like most of his generalizations, there is little further development, not directly at least. This one asserts that *all* interaction carries with it the risk of exposure to a painful emotion. One of Goffman's main ideas, *impression management*, has a similar implication. The reason we spend such time and care managing our impressions, Goffman argued, is to avoid embarrassment as best we can. Cooley had laid the groundwork for the idea that human life is haunted, if not controlled, by shame, although Goffman does not cite him in this regard.

In two brief statements, Cooley implied that both inner and outer human life produces emotions and that both social and self process *always* leads to either pride or shame.

A. "We live in the minds of others without knowing it." (p. 208).
B. "[The self] seems to have three principal elements:
   1. The imagination of our appearance to the other person
   2. The imagination of his [or her] judgment of that appearance
   3. Some sort of self-feeling, such as pride or [shame]." (p. 184).

Sentence A describes the basis for all social relationships, a theory of mind. Intersubjectivity is built into human nature, yet modern societies make it almost invisible. Small children learn to go back and forth between own point of view and imagining that of the other(s). By the age of five or six, they have become so adept and lightening quick that they forget they are doing it. In Cooley's words, it's like "the ground that bears us up when we walk," taken for granted. The intersubjective bond to others becomes invisible, at least in Western societies.

Human communication is built upon intersubjective guessing because actual speech is complex, fragmented, contextualized, and therefore, if understood literally, usually misunderstood or uninterruptable. To try to understand, the listener must move back and forth between own point of view and the imagined point of view of the speaker. G.H. Mead (1934) called it 'role-taking,' although it is not about roles, but points of view.

Occasionally, role-taking will be referred to in ordinary conversation, but only casually and in passing. For example, one might say to a friend, "We both know that (such and such…)." Even here, in the very act of imaginative mind reading, we usually are not conscious that we are doing it.

Paragraph B proposes a *looking glass self*, the way in which social relationships give rise to a self, which, in turn, leads to pride or shame. Cooley's approach implies that all social interaction produces either pride or shame and that these emotions are social as well as psychological. They signal the state of the relationship: either *connectedness* (pride) or *disconnect* (shame). It further implies that the degree of solidarity or alienation (connect/disconnect) determines the prevailing emotional states in a society.

The paragraph also suggests how, in three steps, either pride or shame might be present all of the time, whether one is alone or with others. The two passages together imply a basis for what will be called the Elias–Lewis conjecture: *shame or its anticipation is ubiquitous in modern societies, yet it also has become largely invisible*. But what about pride?

Cooley's and Goffman's treatment of the looking glass self are quite parallel. Cooley's few concrete examples all concern shame rather than pride. Goffman provided hundreds of examples of impression management, but none ending in genuine pride. There are 16 mentions of either shame or embarrassment in the text of *Presentation of Self in Everyday Life* (1959), but only three of pride. Moreover, all three of the pride mentions were in long quotes by other authors, in which pride was largely incidental. Goffman himself uses only shame terms, not pride. Why did both authors omit it?

Though neither Cooley nor Goffman name the kind of civilization they analyzed, it is clearly the current one, a modern, rather than a traditional society. Perhaps modernity gives rise to their single focus on shame. Shame is a signal of disconnect, alienation. Relationships in modern societies strongly tend toward alienation, and therefore to the ubiquity of shame.

Modernity is built on a base of individualism, the encouragement to go it alone, no matter the cost to relationships. Persons learn to act as if they were complete in themselves and independent of others. This feature has constructive and creative sides, but it has at least two other ones: alienation and the hiding of shame.

Emphasis on individual rationality is a key institution in modern societies. Another is the suppression of the social–emotional world in favor of thought and behavior. One of the many outcomes of this suppression is that emotion vocabularies in modern languages are ambiguous and misleading, so that they tend to hide alienation. For example, in the English language, love is defined so broadly that is often used to hide disconnection (*Women Who Love Too Much*). There are also many other ambiguities, confusions, and deceptions. Since shame is elaborately hidden and disguised, a close examination of the verbal, gestural, and contextual details may be needed to uncover it.

In traditional and Asian societies, the central importance of shame is taken for granted. Indeed, in some Asian societies, such as Japan, it is seen as the central emotion. In a traditional society like the Maori, shame (they call it *whakamaa*) is also treated as the key emotion. Indeed, the whole approach to shame and relationships in this article would be seen as platitudes by the Maori, news from nowhere. But in Western societies, treating shame as highly significant in everyday life is counterintuitive and even offensive.

Western societies focus on individuals, rather than on relationships. Emerson, because of his emphasis on self-reliance as an antidote to blind conformity, was one of the prophets of individualism: "When my genius calls, I have no father and mother, no brothers or sisters." In extreme contrast, in a traditional society, there is *nothing* more important than one's relationships. Freeing up the individual from their relational/emotional world has been at the core of modernization. Since one's relationships and emotions do not show up on a resume, they have been de-emphasized to the point of disappearance. But shame and relationships do not disappear; they just assume hidden and disguised forms.

Individualism is the dominant theme of all relationships in Western societies. This focus disguises the web of personal and social relationships that sustain all human beings. The myth of the self-sustaining individual, in turn, reflects and generates the suppression and hiding of shame and pride. Since pride and shame, or at least their anticipation, are the predominant emotions in social interaction, suppression supports the status quo, the myth of the self-contained individual. But the obverse is that as we become aware of the massive amounts of emotions and disguising of emotion that occur in social interaction, *we can make visible what is otherwise invisible, the state of any given relationship or set of relationships*.

Pride, Shame, and Alienation

The confusion of English vernacular is obvious in the case of pride, since dictionaries and usage both imply two contradictory meanings. The first meaning is negative: pride is interpreted as egotism ('Pride goeth before the fall'). When we say that someone is proud, it is likely to be condemnatory. *False pride* might be a better name for this kind of self-feeling to distinguish it from true pride.

The second meaning is positive: a favorable view of self, but one that has been earned. This kind of pride is genuine, authentic, justified. However, even adding these adjectives does not completely eliminate the negative flavor. In English, the

word pride is often tainted by its first meaning, no matter how impressive the justification.

Individualism also causes endless obfuscation about shame. The primary confusion is the practice of leaving out the social component that arises from the looking glass self: viewing ourselves negatively because we imagine that we are viewed that way by another person or persons.

Both in vernacular and in scholarly usage, shame typically is assumed to be only an internal matter, condemning oneself. But the looking glass self contains both the internal result and the external source. The typical definition of shame in psychological studies involves gross dissatisfaction with self. Cooley's usage includes this part, but also the social component, imagining, correctly or incorrectly, a negative view of self by others.

Cooley's idea of the social source of shame and pride suggests that these emotions are signals of the *state of a relationship*. As indicated earlier, whatever the substantive basis for shame, the actual violation or occasion, a more general component is the state of the bond: *true pride signals a secure bond (connectedness), shame a threatened one (disconnect)*. This definition virtually always includes the substantive cause of shame, whatever it might be, since the causes of shame themselves are usually shared with one's whole society.

Since modern societies produce alienation at many different levels, emotions and relationships are deeply hidden. Shame, in particular, becomes invisible, even for most social and behavioral researchers. A taboo is implied in the many studies of shame that do not use the forbidden word at all. Instead, the focus is on one of the many shame cognates (Retzinger, 1995, lists hundreds). One such cognate is the word awkward, as in 'it was an awkward moment for me.' A further way of hiding shame is to behaviorize it: there are many studies of feelings of *rejection*, *loss* of social status, and the *search* for recognition.

I have just begun to study the occurrence of shame and other emotion terms in millions of digitalized books from 1800 to 2000. These data are called Ngrams by its makers, Aiden (2011). My initial finding is that the use of the word shame has decreased threefold during the 200 years covered by the Ngrams. This issue is somewhat complex, since phrases that use the word do not refer to actual shame: 'What a shame!' means exactly the same thing as 'What a pity.' I will describe all of the findings in a later report.

Lewis's study of shame in psychotherapy sessions, to be discussed later, has received many citations, yet they usually ignore or misinterpret her main findings. She complained to me once that people praise her book but do not read it. Similarly, groups headed by Paul Gilbert and George Brown have published several studies of shame, but with little response.

On the other hand, Evelin Lindner has been able to organize a worldwide following for the study of themes identical to those discussed here. Her success may be due, at least in part, to avoiding the s-word, especially in titles, not only for her organization (*Human Dignity and Humiliation Studies*), but also for her books. Another instance is the work of Robert W. Fuller. He has been able to speak to large audiences all over the world using title words like Lindner's and avoiding the s-word.

The taboo on shame seems to have weakened in the last 10 years among researchers. The downward slope for the word shame has slowed in the Ngrams. But it continues to exert a powerful influence in the vernacular and even in research: shame is still close to being unspeakable and unprintable. The next section will outline a theory that can be used to explain this taboo and the possibility that it can have destructive effects.

Cooley's Brief Examples and Goffman's Lack of Explicit Theses

Cooley offered only brief explication of his two propositions, as in this passage that introduces his idea that we usually do not know that we are living in the minds of others and producing emotions. We only realize it, he states, in extreme or unusual situations:

> Many people of balanced mind…scarcely know that they care what others think of them, and will deny, perhaps with indignation, that such care is an important factor in what they are and do. But this is an illusion. If failure or disgrace arrives, if one suddenly finds that the faces of men show coldness or contempt instead of the kindliness and deference that he is used to, he will perceive from the shock, the fear, and the sense of being outcast and helpless, that he was living in the minds of others without knowing it, just as we daily walk the solid ground without thinking how it bears us up (1922, p. 208).

In the following passage, Cooley explains how the looking glass self generates shame:

> The comparison with a looking glass hardly suggests the second element, the imagined judgment, which is quite essential. The thing that moves us to *pride or shame is* not the mere mechanical reflection of ourselves, but an imputed sentiment, the imagined effect of this reflection upon another's mind. This is evident from the fact that the character and weight of that other, in whose mind we see ourselves, makes all the difference with our feeling. We are *ashamed* to seem evasive in the presence of a straightforward man, cowardly in the presence of a brave one, gross in the eyes of a refined one, and so on. We always imagine, and in imagining share, the judgments of the other mind. A man will boast to one person of an action – say some sharp transaction in trade – which he would be *ashamed* to own to another (1922, pp. 184–185, emphasis added).

This discussion suggests less abstract situations. In the following passage, Cooley refers to particular, though fictional, events in novels, but without quoting any of them in detail:

> In most of [George Eliot's] novels there is some character like Mr. Bulstrode in *Middlemarch*….whose respectable and long established social image of himself is shattered by the coming to light of hidden truth (1922, p. 208).

Cooley's statement, since it is abstract, gives only a slight sense of how catastrophic the shattering of the social image is, and how far it reaches. In the novel, Bulstrode's wife, Dorothea, although blameless, stands by her disgraced husband. The novel provides detailed particulars so that the reader is alerted to the full force of public humiliation. Using Bulstrode's instance to make his point is somewhat of a departure from Cooley's tendency to abstain from description. However, he

does not go so far as to quote the passage and comment on how the details in it relate to his thesis, as Goffman does.

Here, for example, is a quotation showing one way Bulstrode's disgrace reaches to his wife. Cooley could have used this to illustrate the particulars of his thesis:

> When she had resolved to [stand by her husband], she prepared herself by some little acts which might seem mere folly to a hard onlooker; they were her way of expressing to all spectators visible or invisible that she had begun a new life in which she embraced humiliation. She took off all her ornaments and put on a plain black gown, and instead of wearing her much-adorned cap and large bows of hair, she brushed her hair down and put on a plain bonnet… (Eliot, 1900, p. 338).

Dorothea prepares for a public stripping of her dignity by discarding her socially acceptable appearance, replacing it with what might have been prison or funeral clothing. By only referring to events like this one, rather than quoting them, Cooley was unable to describe the full force of his ideas.

Goffman, on the other hand, freely used a great multitude of concrete examples. His wealth of detailed events may be the key to his popularity and his importance. They remind readers of their own instances: 'That's like me!' They can also be used to illustrate many of Cooley's theses.

Here is an example of a Goffman instance that illustrates Cooleyean themes, with numbers added to help the reader keep track:

> Knowing that his audiences are capable of forming bad impressions of him [1], the individual may come to feel ashamed [2] of a well-intentioned honest act merely because the context of its performance provides false impressions that are bad. Feeling this unwarranted shame, he may feel that his feelings can be seen [3]; feeling that he is thus seen, he may feel that his appearance confirms [4] these false conclusions concerning him. He may then add to the precariousness of his position by engaging in just those defensive maneuvers [impression management] that he would employ were he really guilty. In this way it is possible for all of us to become fleetingly for ourselves the worst person we can imagine that others might imagine us to be (1959, p. 236, numbering added).

This instance is somewhat difficult to understand because it is so complex. It would have helped if Goffman had been even more detailed. Suppose a jokester colleague at the office creates a forbidden sound by pressing a whoopee cushion just as you sit down at your desk. You are embarrassed (2), because you imagine that your colleagues think it was you who made the sound (1). Even though you are not the culprit, you blush (3) because you imagine the others in the office think it was your inappropriate action (4).

In this paragraph, Goffman suggested four very brief internal steps, three of which involve living in the mind of the other. Perhaps it was examples like these that led Bourdieu (1983) to call Goffman 'the discoverer of the infinitely small.' The minuteness about Goffman's particulars like this one is the time scale: perhaps portions of a second for each event that is described. So far the discussion has been about theories of shame. Next comes two studies that seem to support the theories.

Elias on European History

In an extraordinary study over hundreds of years of European history, sociologist Norbert Elias analyzed etiquette and education manuals in five different languages. (*The Civilizing Process* 1939. First translated from German into English in 1978.) There are two main themes: as physical punishment decreased, shame became increasingly dominant as the main agent of social control; and as shame became more prevalent, it also became almost invisible because of taboo.

The following excerpt gives the flavor of Elias's study. It is from a nineteenth-century work (von Raumer, 1857) that advises mothers how to answer the sexual questions their daughters ask:

> Children should be left for as long as possible in the belief that an angel brings babies. If girls should later ask how children come into the world, they should be told that the good Lord gives the mother her child…"You do not need to know nor could you understand how God gives children." It is the mother's task to occupy her daughters' thoughts so incessantly with the good and beautiful that they are left no time to brood on such matters. A mother … ought only once to say seriously: "It would not be good for you to know such a thing, and you should take care not to listen to anything said about it." A truly well brought-up girl will from then on feel shame at hearing things of this kind spoken of (1978, p. 180).

Elias First Interprets the Repression of Sexuality in Terms of Hidden Shame:

> An aura of embarrassment…surrounds this sphere of life. Even among adults it is referred to officially only with caution and circumlocutions. And with children, particularly girls, such things are, as far as possible, not referred to at all. von Raumer gives no reason why one ought not to speak of it with children. He could have said it is desirable to preserve the spiritual purity of girls for as long as possible. But even this reason is only another expression of how far the gradual submergence of these impulses in shame and embarrassment has advanced by this time (1978, p. 180).

Elias raises a host of significant questions about this excerpt, concerning its motivation and its effects. His analysis goes to what may be a key causal chain in modern civilization: denial of shame and of the threatened social bonds that both cause and reflect that denial.

> Considered rationally, the problem confronting him [von Raumer] seems unsolved, and what he says appears contradictory. He does not explain how and when the young girl should be made to understand what is happening and will happen to her. The primary concern is the necessity of instilling 'modesty' (i.e., feelings of shame, fear, embarrassment, and guilt) or, more precisely, behavior conforming to the social standard. And one feels how infinitely difficult it is for the educator himself to overcome the resistance of the shame and embarrassment which surround this sphere for him (1978, p. 181).

Elias's study suggests a way of understanding the social transmission of the taboo on shame and the social bond. The adult teacher, von Raumer, in this case, is not only ashamed of

sex, he is ashamed of being ashamed. The nineteenth-century reader, in turn, probably reacted in a similar way: being ashamed, and being ashamed of being ashamed, and being ashamed of causing further shame in the daughter. von Raumer's advice was part of a social system in which attempts at civilized delicacy resulted and continue to result in an endless chain reaction of hidden shame.

Elias understood the significance of the denial of shame to mean that shame goes underground, leading to behavior that is outside of awareness:

> Neither rational motives nor practical reasons primarily determine this attitude, but rather the shame (*scham*) of adults themselves, which has become compulsive. It is the social prohibitions and resistances within themselves, their own superego, that makes them keep silent (1978, p. 181).

Like many other passages, this one implies not only to a taboo on shame, but to the actual mechanisms by which it is transmitted and maintained.

Helen Lewis's Study of Psychotherapy Sessions

Helen B. Lewis, a research psychologist, used a systematic method to locate verbal emotion indicators in many transcriptions of psychotherapy sessions. She seems to have been unaware of Elias's study. She found, to her surprise, that shame/embarrassment was by far the most frequent emotion, occurring more often than all the other emotions combined. She also found that these instances of shame/embarrassment, unlike joy, grief, fear, or anger, were virtually never mentioned by either the client or the therapist. She called the unmentioned instances 'unacknowledged shame.' Her findings provide support, at the word by word level, for Elias's thesis of the prevalence and invisibility of shame at the historical level.

She also found that the shame in these episodes seemed to be hidden in two different ways. *Overt, undifferentiated shame* (OUS) involved painful feelings that were hidden behind terms that avoided the s-word (Elias used the word 'circumlocutions'). *Bypassed* shame involved rapid thought, speech, or behavior, but little feeling. OUS is marked by pain, confusion, and bodily reactions such as blushing, sweating, and/or rapid heartbeat. One may be at a loss for words, with fluster or disorganization of thought or behavior, as in states of embarrassment.

Many of the common terms for painful feelings appear to refer to OUS: feeling peculiar, shy, bashful, awkward, funny, bothered, or miserable; in adolescent vernacular, being freaked, bummed, or weirded out. The phrases 'I felt like a fool,' or 'a perfect idiot' are prototypic. Some of the substitute terms involve phrases. The example used earlier, 'an awkward moment': It's not me that embarrassed (denial), but the moment that is awkward (projection). As indicated above, Retzinger's article (1995) lists over a 100 substitute words and phrases.

Bypassed shame is manifested as a brief painful feeling, usually fleeting, followed by obsessive and rapid thought or speech. A common example: one feels insulted or criticized. At that moment (or later in recalling it), one might experience a very brief jab of painful feeling, followed immediately by imaginary replays of the offending scene. The replays are variations on a theme: how one might have behaved differently, avoiding the incident, or responding with better effect. One is obsessed.

It seems to me that Lewis's use of a systematic method to detect emotion terms and cognates might have led to underreporting of shame episodes. Her finding of episodes of bypassed shame would be one reason, since the method she used would be better at locating OUS terms, sometimes missing the obsessive talk and/or thinking that characterize bypassed shame.

Elias's method was unsystematic, and for that reason, probably much broader than Lewis's. He examined all topics that frequently occur in the books he examined: sexuality, body functions, modesty, delicacy, manners, embarrassment, and what he named 'sociogenetic fear.' By the last phrase he was not referring to fear in the sense of a response to physical danger. Rather, he used it as another way of referring to shame. This kind of sidestepping of the s-word occurs frequently in everyday conversations: 'I fear rejection' has nothing to do with physical danger: it usually means 'I anticipate shame.'

Both the study by Elias and the one by Lewis can be seen as hinting that shame might be ubiquitous yet invisible in modern societies, but neither makes that point explicitly.

How Secret Shame Can Lead to Silence or Violence

Goffman also added a further thesis to the looking glass self, a fourth step to the three proposed by Cooley: managing (such as hiding) shame that could not be avoided. Furthermore, there is a fifth step barely hinted at by Goffman: hiding shame during the fourth step can generate a fifth step in the form of behavior. Helen Lewis (1971) noted that shame may result in withdrawal or even depression, on the one hand, or anger and aggression, on the other. The work of Retzinger (1991), the psychiatrist Gilligan (1997), and the sociologist Websdale (2010) follow-up on the latter direction. These four studies show how the escalation of anger and violence is caused by hidden shame.

> The emotion of shame is the primary or ultimate cause of all violence… The different forms of violence, whether toward individuals or entire populations, are motivated (caused) by *secret* shame (1997, pp. 110–111).

Gilligan's theory is of great interest, since it proposes an emotional cause for both interpersonal and mass violence. Websdale's (2010) study of 211 cases of familicide found strong support for Gilligan's thesis. A finding of particular interest in his study was the sizable minority of perpetrators who had what he calls a *civic-respectable* (C-R) style, in contrast to the majority whose style was angry and aggressive.

The C-R killers had no history of violence and little evidence even of anger. They were almost all middle class men (and a few women) who had lost their jobs. They hid the fact by continuing to leave the house every weekday as if going to work. What they did during their absence was to plan in detail

the killing of their family, and often, themselves. Proud of their abilities as a breadwinner, they apparently could not bear the humiliation of being jobless.

This C-R style of violence, it seems to me, has deep parallels to the preparation of nations for wars of revenge, as was the case of France preparing to make war on Germany in the period 1871–1914 (Scheff, 1997). Especially for the leaders, both shame and anger are carefully hidden behind a veil of rationality. The Bush administration may have been deeply embarrassed by the 9/11 attack during their watch and their helplessness to punish the attackers. The invasion of Iraq on the basis of false premises might have served to hide their shame and anger. The idea of the looking glass self, especially when it is expanded to at least five steps, can serve to generate a large group of general propositions about both interpersonal and collective behaviors.

Neither Cooley nor Goffman dealt with the idea of justified pride, nor have many others. Cooley discussed pride and vanity (1922, pp. 230–237), but his version of pride confounds it with egotism, the usual case in vernacular English. Tracy et al. (2009) have recently noted this confound, distinguishing between what they call authentic (justified) and hubristic pride (egotism).

Conclusion

This article has reviewed four master studies of shame and its place in human life. Two of the studies were articles that imply a theory of shame, giving rise to what might be called the Cooley/Goffman conjecture. Two were empirical studies that seem to support the theory. In its most general terms, it proposes that shame or its anticipation is virtually ubiquitous, yet usually invisible in modern societies. This idea seems to be strongly supported by the substantial empirical studies made by Elias of macrohistory and Lewis of the microworld of social interaction. The theory needs to be further and more directly tested. If further studies support it, perhaps social–behavioral science and psychiatry need to proceed in a new direction.

Shared Belief: Philosophical Aspects

Raimo Tuomela, University of Helsinki, Helsinki, Finland; and University of Munich, Munich, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The importance of the notion of shared belief has been emphasized by philosophers, economists, sociologists, and psychologists at least since the 1960s. This article concentrates on the strongest kind of shared belief, to be called 'mutual belief.' While a belief can be shared in the trivial sense of two or more people having the same belief, mutual belief requires the kind of strong sharing that requires at least the participants' awareness (belief) of their similar belief. Mutual belief is one central kind of collective attitude; examples of others are collective intentions, wants, hopes, and fears. Understandably, collective attitudes are central explanatory notions for the social sciences, as one of their tasks is to study collective phenomena, including various forms of collective thinking and acting. As to mutual beliefs, they serve to characterize social or intersubjective existence in a sense not relying on the making of agreements or contracts. Thus, many social relations, properties, and events – including intentional communication – arguably involve mutual beliefs. Furthermore, characterizations of many other collective attitudes depend on the notion of mutual belief. This article discusses various kinds of shared belief and the problem of whether and when several iterated beliefs are needed. While the emphasis is on individual-mode beliefs, it is pointed out that in full-blown group contexts, special group-mode (or 'we-mode') beliefs will be required of the group members.

Introducing the Concept of Shared Belief

The importance of the notion of shared belief has been emphasized by philosophers, economists, sociologists, and psychologists at least since the 1960s (earlier contributors include Schelling, 1960; Scheff, 1967; Lewis, 1969; Schiffer, 1972). This article deals with the strongest kind of shared belief, to be called 'mutual belief.' While a belief can be shared in the trivial sense of two or more people having the same belief, mutual belief requires the kind of strong sharing that requires at least the participants' awareness (belief) of their similar belief. Mutual belief is one central kind of collective attitude; examples of others are collective intentions, wants, hopes, and fears. Understandably, collective attitudes are central explanatory notions in the social sciences, as one of the tasks of these sciences is to study collective phenomena, including various forms of collective thinking and acting (illustrations are given in this article).

There is some special, additional interest in the notion of shared belief as mutual belief. First, mutual beliefs serve to characterize social or intersubjective existence in a sense that does not rely on the participants making agreements or contracts. Thus, many social relations, properties, and events arguably involve mutual beliefs (cf. Lewis, 1969; Ruben, 1985; Lagerspetz, 1995; Tuomela, 1995). As a simple example, think of the practice of two persons, *A* and *B*, shaking hands. It presupposes that *A* believes that *B* and *A* are shaking hands, and that *A* also believes that *B* believes similarly; and *B* must believe analogously. Similarly, communication has been argued by many philosophers, especially Grice, to involve mutual belief (cf. Schiffer, 1972; Grice, 1989). Second, characterizations of many other collective attitudes in fact depend on the notion of mutual belief (cf. Balzer and Tuomela, 1997).

In social psychology and sociology, theoreticians often speak about *consensus* instead of mutual belief. The notion of consensus – with the core meaning 'mutual belief' – has been regarded as relevant to such topics as public opinion, values, mass action, norms, roles, communication, socialization, and group cohesion. It can also be mentioned that fads, fashions, crazes, religious movements, and many other related phenomena have been analyzed partly in terms of shared beliefs, consensus, shared consensus, mutual belief, or some similar notions. As pointed out by the sociologist Scheff (1967), such analyses have often gone wrong because they have treated consensus merely as a shared first-order belief. Thus, as Scheff argues, consensus as mere first-order agreement does not properly account for 'pluralistic ignorance' (where people agree but do not realize it) or 'false consensus' (where people mistakenly think that they agree). Scheff proposes an analysis in terms of levels of agreement corresponding to a hierarchy of so-called loop beliefs (e.g., in the case of two persons *A* and *B*, *A* believes that *B* believes that *A* believes that something *p*). As is easily seen, pluralistic ignorance and false consensus are second-level phenomena. The third level will have to be brought in when speaking about people's awareness of these phenomena. Other well-known social psychological notions requiring more than shared belief are Mead's concept of 'taking the role of the generalized other,' Dewey's 'interpenetration of perspectives,' and Laing's metaperspectives (see, e.g., Scheff, 1967).

There are two different conceptual–logical approaches to understanding the notion of mutual (or, to use an equivalent term, common) belief: (1) the *iterative* account, and (2) the *reflexive* or *fixed-point* account. According to the iterative account, mutual belief is assumed to mean iterable beliefs or dispositions to believe (cf. Lewis, 1969, Chapter 2 and for the weaker account in terms of dispositions to come to believe, Tuomela, 1995, Chapter 1). In the two-person case, mutual belief amounts to this according to the iterative account: *A* and *B* believe that *p*, *A* believes that *B* believes that *p* (and similarly for *B*), *A* believes that *B* believes that *A* believes that *p* (and similarly for *B*), and the iteration can continue as far as the situation demands. In the case of loop beliefs, there is accordingly mutual awareness only in a somewhat rudimentary

sense. As will be seen, in many cases one needs only two iterations for functionally adequate mutual belief: *A* and *B* believe that *p*, and they also believe that they believe that *p*. However, there are other cases in which it may be needed to go higher up in the hierarchy.

The fixed-point notion of mutual belief can be stated as follows: *A* and *B* mutually believe that *p* if and only if they believe that *p* and also believe that it is mutually believed by them that *p*. No iteration of beliefs is at least explicitly involved here. Correspondingly, a clear distinction can be made between the iterative or level account and the fixed-point account (to be briefly commented on in Section Mutual Belief as Shared We-Belief).

One can speak of the individual (or personal) mode and the group mode of having an attitude such as a belief or intention. This article deals with the general notion of mutual belief, be it in the individual mode or in the group mode. Some remarks on the present distinction are anyhow appropriate here. The group-mode sense, expressible by 'We, as a group, believe that *p*,' requires that the group in question is collectively committed to upholding its mutual belief or at least to keeping the members informed about whether it is or can be upheld. This contrasts with mutual belief in an aggregative individual mode involving only personal commitments to the belief in question. When believing in the group-mode sense, group members are accordingly committed to a certain shared view of a topic and to group-mode thoughts such as 'We, as a group, believe that *p*.' Group-mode beliefs are central in the analysis of the kinds of beliefs that structured social groups such as organizations and states have. According to the 'positional' account defended by Tuomela (1995), the group members authorized for belief or view formation collectively accept the views that will qualify as the beliefs the group has. These views are group-mode views accepted for the group and are, strictly speaking, acceptances of something as the group's views rather than beliefs in the strict sense.

Mutual Beliefs More Precisely Characterized

This section will be concerned with what mutual beliefs involve over and above plain shared beliefs, and Section Mutual Beliefs and the Level Problem takes up the problem of how many layers of hierarchical beliefs are conceptually or psychologically needed. (The discussion below draws on the treatment in Tuomela (1984, 1995).)

Consider now the iterative account starting with the case of two persons, *A* and *B*. Recall from Section Introducing the Concept of Shared Belief that, according to the standard iterative account, *A* and *B* mutually believe that *p* if and only if *A* believes that *p*, *B* believes that *p*, *A* believes that *B* believes that *p* (and similarly for *B*), *A* believes that *B* believes that *A* believes that *p* (and similarly for *B*), and so on, in principle *ad infinitum*. In the general case, the account defines that it is mutually believed in a group, say *G*, that *p* if and only if (1) everyone in *G* believes that *p*, (2) everyone believes that everyone believes that *p*, (3) everyone believes that everyone believes that everyone believes that *p*, (4) and so on *ad infinitum*. The word 'everyone' can, of course, be qualified if needed and made dependent on some special characteristics; for example, it can be restricted to concern only every fully fledged, adequately informed, and suitably rational member of the group.

A major problem with the iterative account is that it seems in some cases to be psychologically realistic. It loads the people's minds with iterated beliefs that people, after all, do not experientially have and possibly, because of lack of rationality and memory, cannot have. Thus, the account must be improved to make it better correspond to psychological reality. One way to go is to operate partly in terms of lack of disbelief. A person's lack of disbelief that *p* is defined as it is not the case the person believes the negation of *p*. One can try to define mutual belief schematically by saying that it is mutually believed in *G* that *p* if and only if everyone believes that *p*, iterated *n* times, and from level $n+1$ on everyone lacks the disbelief that *p*. With $n = 2$ (viz., two levels actually present), this definition says that mutual belief amounts to everyone believing that *p* and everyone believing that everyone believes that *p* and that everyone lacks the disbelief that *p* from the second level on.

The basic reason for using this amended iterative approach is that no more levels of positive belief than people actually have should be required. Provided that the value of *n* can be established, the present account satisfies this. It must be assumed here that the agents in question are to some degree intelligent and rational as well as free from emotional and other disturbances so that they, for instance, do not lack a higher-order belief when they really ought to have one in order to function optimally.

While the iterative account amended with the use of the notion of lack of disbelief seems viable for some purposes, an alternative analysis is worth mentioning. This analysis amends the original iterative account in that it requires iterative beliefs up to some level *n* and from that level on requires only the disposition to acquire higher-order beliefs in appropriate conditions. These appropriate conditions, serving to determine the value of *n*, include both background conditions and more specific conditions needed for acquiring the belief in question. First, the agents in *G* must be assumed to be adequately informed and share both general cultural and group-specific information; especially, they must have the same standards of reasoning so that they are able to 'work out the same conclusions' (see Lewis, 1969, Chapter 2; Heal, 1978). Second, they must be sufficiently intelligent and rational, and they must be free from cognitive and emotional disturbances to a sufficient degree (so that there are no psychological obstacles for adding the $n+1$st order belief when a genuine mutual belief is involved and for not adding it, or indeed for adding its negation, when a genuine mutual belief is not involved). A typical releasing condition for the disposition to acquire a higher-order belief would be simply that the agents are asked about higher-order beliefs (or are presented with other analogous problems concerning them).

There is not much to choose between the two amended accounts, and the matter will not be discussed further here. With the conceptual machinery at hand, one can deal with, for instance, the mentioned phenomena of pluralistic ignorance and false consensus. An account of pluralistic ignorance, concerning something *p*, must obviously include the idea that everyone believes that *p*. Second, it must say that the agents do not have the belief that they agree. Compatibly with this, it can still be required that they do not disbelieve that they believe

that p. As to false consensus, it must be required that not everyone believes that p and that, nevertheless, it is believed by everyone that everyone believes that p.

Mutual Beliefs and the Level Problem

Let us next discuss the level problem. Given the iterative account, the problem is how many iterative levels of belief are conceptually, epistemically, or psychologically needed for success in various cases. The criteria here are functionality and success. For instance, how many levels of belief does successful joint action require? The level question is difficult to answer in general terms. However, it can be conjectured that in certain cases at least two levels (viz., $n = 2$), relative to the base level, are needed for mutual belief, but no more. In some other cases, this is not enough. Generally speaking, there are very seldom epistemic or psychological reasons for going beyond the fourth level. For many agents, level $n = 4$ probably is psychologically impossible or at least very difficult to handle in one's reasoning.

The base level is level 0, at which the sentence or proposition p is located, and p will concern or be about an agent's or agents' actions, dispositions to act, intentions, beliefs, or something related; or, alternatively, p can be (or concern) a belief content. In the analysis below, it is accepted that the beliefs – at least those going beyond the level $n = 2$ – need not be proper occurrent or standing beliefs or even subconscious ones but only dispositions to form the belief in question (see Audi, 1994 for the relevant notion of a disposition to form a belief).

The claim that $n = 2$ is not only necessary but also sufficient in many typical cases is allowed to involve social loop beliefs where the content of mutual belief could be, for instance, that A believes that B believes that A will act in a certain way, or believes that such and such is the case. What the base level will be is relative to the topic at hand. That at least two levels are needed can be regarded as a conceptual truth (related to the notion 'social existence'); and that in many typical cases no more is needed or, in some other cases, four layers are needed can be regarded as general psychological theses concerning the actual contents of people's minds in those situations.

The present view allows that a need may arise to add layers indefinitely. There follows a recursive argument to show that such a situation is possible in principle. Given an analysis of mutual belief in terms of iteration of beliefs such as ours, then at each level under consideration one may start asking questions about people's realizing (or believing) such and such, where 'such and such' refers to the level at hand. This game obviously can go on indefinitely as far as the involved agents' reasoning capacities (or whatever relevant capacities) permit. This is an inductive argument (in the mathematical sense – the first step is obvious) for the open and infinite character of the hierarchy of nested beliefs.

To discuss the level problem in more concrete terms, let us consider mutual belief in the case of two agents, A and B. First, we let our base-level sentences be related to the agents' performances of their parts as follows:

(a) A will do his part of X (in symbols, $p(A)$);
(b) B will do his part of X ($p(B)$).

Next, let us assume:

(i) A believes that (a) and (b);
(ii) B believes that (a) and (b).

This is a social or mutual recognition of the agents' part-performances in the context of joint action.

The sentence p in (a) and (b) may alternatively concern other things than action. Thus it may represent a belief content, for example $p =$ The earth if flat, and we will consider this case below.

Considering joint action, it can be argued that $n = 2$ is both necessary and sufficient for successful performance. In this example, A will obviously have to believe that B will do her part. This gives her some social motivation to perform her own part. Concentrating on our reference point individual A and genuine joint action X (in which the agents' performances of their parts are interdependent), A must also believe (or be disposed to believe, at any rate, viz., come to form the belief if asked about the matter) that B believes that A will do her part. For otherwise, A could not believe with good reason that B will do her part, for B would – if she does not so believe – lack the social motivation springing from her belief that A will do her part. However, if she did lack that motivation, A could not on this kind of ground defensibly form the belief that B will perform her part. This argument shows that it must be required that the agents have a loop belief or at least a disposition to have a loop belief:

(iii) A believes that (i) and (ii);
(iv) B believes that (i) and (ii).

For instance, (iii) gives the loop 'A believes that B believes that $p(A)$,' and this means that in the present kind of case, $n = 2$ is necessary and normally also sufficient (relative to the chosen base level).

An analogous claim can be defended in the case of belief. Here the defense can be given in terms of the recognition by the agents that they share a belief. Suppose not only that each member of the Flat Earth Society believes that the Earth is flat, but also that – because of being organized into a belief group – the members all share this information. This second-order belief indicates the first level at which social and mutual belief can be spoken of in an interesting sense, for at this level people recognize that the others in the group believe similarly, and this establishes a doxastic social connection; at level one that recognition is, however, missing. This is a typical case of a social property, and again $n = 2$ is both necessary and normally sufficient for acting in matters related to the shape of the Earth *qua* a member of the society.

Suppose now the members of the Flat Earth Society begin to reflect upon this second-order belief of theirs and come to form the belief that indeed it does exist. (Perhaps a sociologist has just discovered that they share the second-order belief and told them about it.) They might wonder how strong this second-order awareness is, and so on. All this entails that on some occasions, third-order beliefs may be needed, although the standard case clearly would be second-order beliefs accompanied by a disposition to go higher up if the need arose. Analogously, in the case of joint action in some very special cases, for example, double loop beliefs may be needed for rational action.

The reader should be reminded that not all social notions depend on mutual belief. For instance, latent social influence and power do not require it, nor does a unilateral love relation between two persons.

Mutual Belief as Shared We-Belief

What have been called 'we-attitudes' are central for an account of social life (see Tuomela, 1995, Chapter 1; Tuomela and Balzer, 1999). A we-attitude is a person's attitude (e.g., belief, want, or fear) concerning something p (a proposition or sentence) such that (1) this person has the attitude in question and believes that (2) everyone in the group has the attitude and also believes that there is a mutual belief to the effect that (2) in the group. Of these, clause (1) is required because there cannot of course be a truly shared attitude without all the members participating in that attitude. Clause (2) gives a social reason for adopting and having the attitude A, and (3) strengthens the reason by making it intersubjective. (A shared we-attitude can be either in the group mode or in the individual mode; cf. Section Introducing the Concept of Shared Belief.)

A shared we-belief is a we-belief (be it in the individual or in the group mode) that (ideally) all the group members have. To take an example, a shared we-belief that the Earth is flat entails that the group members believe that the Earth is flat, and also that it is a mutual belief in the group that the group members believe that the Earth is flat.

Shared we-beliefs can be related to the reflexive or fixed-point account of mutual belief. According to the simplest fixed-point account, mutual belief is defined as follows: it is a mutual belief in a group that p if and only if everyone in the group believes that p and also that it is mutually believed in the group that p. It can thus be seen that the account of mutual belief given by the fixed-point theory is equivalent to the definiens in the definition of a shared we-belief. In the fixed-point approach, the syntactical infinity involved in the iterative approach is cut short by a finite fixed-point formula that is an impredicative construct in which the joint notion to be 'defined' already occurs in the definiens. Under certain rationality assumptions about the notion of belief, it can be proved that the iterative approach, which continues iterations *ad infinitum*, gives the fixed-point property as a theorem (see Halpern and Moses, 1992 and for a more general account, Balzer and Tuomela, 1997).

The fixed-point account is in some contexts psychologically more realistic, as people are not required to keep iterative hierarchies in their minds. Note, however, that it depends on context whether the iterative approach or the fixed-point approach is more appropriate. Thus, in the case of successful joint action, at least loop beliefs must be required.

Abstract

The scientific life of Sherrington, born in London in 1857 died in Eastbourne in 1952, is characterized by two main floruits. The first period (1884–1933) with positions in London, Liverpool, and Oxford was occupied by physiological and partly histological investigations of the nervous system. Beside the observation and detailed description of innumerable nervous phenomena, particularly in motor control, Sherrington's, most important contribution to neuroscience resulted from his unique capability to condense his immense knowledge on sensory and motor functions and on the structure of the nervous system in an almost visionary synopsis of the integrative action of the nervous system. His experimentally well-based theories and concepts formed a greatly recognized secure foundation for future developments in neuroscience. During his second period (up to his retirement in Oxford, 1935, and later until his death) Sherrington was mainly dedicated to the philosophy of the central nervous system. Based on his comprehensive knowledge of the nervous system and the field of biology in general, he approached the age-old problem of brain/body–mind relation. Rejecting the assumption of a 'heavenly' origination he defined mind, recognizable by the resulting behavior, as a function of the complex integrative action of the central nervous system.

> Like this old Earth that lolls through sun and shade,
> Our part is less to make than to be made.
>
> Sherrington, 1940, p. 259

To characterize the broad span of Sherrington's engagement he should be described as 'Pathologist, Physiologist, Philosopher and Poet.' It is somewhat arbitrary to pick out only two of them because it is the combination of all these elements that made him both great and unique. However, hardly any other physiologist since 1800 made such a fundamentally important contribution to the knowledge and to the development of concepts in modern neurophysiology. Moreover, when advanced in years, he was the first to attempt a contribution to the solution of the age-old problem of brain/body and mind on a well-founded neuroscientific basis.

The Life

Born in London on 27 November 1857, Sherrington was brought up in Ipswich and Norwich. From his earliest years he felt a strong attraction to poetry, a love which never left him throughout his life. Some of his poems were published in various magazines and later were partly collected in a small volume (Sherrington, 1925).

In 1876 Sherrington first enrolled at St. Thomas' Hospital Medical School in London and in 1881 matriculated at Cambridge University, where he received his BA in 1884 and his MD in 1885. During his undergraduate years he started his research in neuroanatomy and neuropathology, publishing his first papers on these studies in 1884 together with John Newport Langley (Langley and Sherrington, 1884). This was the beginning of a very productive publishing activity with almost 320 scientific publications (for Sherrington's complete bibliography see Fulton, 1952). During his initial postgraduate period at Cambridge Sherrington's scientific interests concentrated on neurohistology and pathology. This period was interrupted by expeditions to epidemics of Asian Cholera in Spain and Italy. The autopsied material taken during these expeditions he analyzed together with J. Graham Brown and Charles S. Roy in England (1885) and with Rudolf Virchow and Robert Koch in Germany (1886). In 1890 Sherrington was appointed lecturer in physiology at St. Thomas' Hospital in London where he mainly performed clinical work. A year later he received the position of the Professor-Superintendent at the Brown Institute at the University of London, where he became remarkably productive with a variety of publications which reflected his pathological, but also his increasing neurophysiological interest. In 1895 Sherrington received his first appointment to a full professorship of physiology at the University College in Liverpool, where he investigated intensely the organization of the spinal cord.

At age 56 (in 1913) Sherrington entered probably the busiest period of his scientific career when he was appointed to the chair of physiology at Oxford University, from which he did not retire until 1935, when he was 78. It was during his Oxford time that he, together with Edgar Adrian, received the Nobel Prize for Medicine in 1932 (the greatest tribute among numerous honours and rewards, like, for example, the Presidency of the Royal Society 1920–25, some 21 international honorary doctorates, and many medals and honorary memberships of British and international societies and academies, among these the corresponding membership of *l'Institut de France*). Three of his students at Oxford were later Nobel Prize winners: Howard Walter Florey, John Carew Eccles, and Ragnar Granit.

In the early 1930s Sherrington performed his last physiological experiments and he felt free to turn to his other great love, the philosophy of the nervous system. Having retired to his old hometown of Ipswich in 1935, his scientific interest was increasingly enriched by philosophical considerations that became evident in the Gifford Lectures, held between 1937 and 1938. Obviously, it was also Sherrington's interest in Natural

Philosophy that caused him to work on Goethe (Sherrington, 1942) and Jean Fernel, a French physician and philosopher of the sixteenth century (Sherrington, 1946).

Though his body was crippled by arthritis, his intellectual capacities remained undimmed until his death in Eastbourne on 4 March 1952.

The Physiologist

Regarding the nervous system as a functional unity resulting from its well-organized parts, Sherrington investigated a variety of motor and sensory systems: the topographical organization of the motor cortex, the binocular integration in vision, as well as the different receptor systems. However, his main efforts concentrated on the spinal cord and its reflex function in motor control. He explicitly admitted that spinal reflex behavior is not 'the most important and far-reaching of all types of nerve behavior' but represents the advantage that 'it can be studied free from complication with the psyche' (Sherrington, 1906/1947, Foreword, p. xiii).

In the spinal cord, isolated from the brain, he carefully analyzed almost all spinal reflex-types from the 'simple' two-neurone reflex arc of the stretch reflex (first described by him), via the complex partly nociceptive flexion and crossed extension reflex and co-ordinated rhythmic scratching and stepping reflexes, up to goal-directed reflex movements of the limbs towards irritating stimuli. Right from the beginning he demonstrated that spinal reflexes are not following a stereotyped all-or-nothing behavior, but that the adaptability of reflexes, based on graduated amplitude, irradiation, and mutual interference between different reflex types, is of great importance for motor control. Sherrington was the first to suggest that inhibition had at least the same functional importance for motor coordination – and other nervous functions – as excitation, not only at the spinal level but also at the brain level and for descending motor commands. This view also opened up new insights into the background of motor disorders observed in various neurological syndromes.

Though some of the reflexes and other motor and sensory phenomena described by Sherrington had been noted earlier, his experimental observations and their analyses were altogether more exact and careful than those of former investigations. Thus, he disproved, e.g., several of Pflügers's reflex laws and the assumption of Descartes (1677) and John and Charles Bell (1826) that reciprocal inhibition is localized peripherally in the muscle. However, the higher experimental sophistication alone would not for sure have received that particularly high enduring recognition. Indeed, Sherrington's most important contribution to neuroscience resulted from his unique capability to condense his immense knowledge on sensory and motor functions and on the structure of the nervous system (partly derived from an intense contact with the famous Spanish neurohistologist Santiago Ramón y Cajal) in an almost visionary synopsis of the integrative action of the nervous system, which laid the foundation for the great progress of neuroscience in the twentieth century and which has lost none of its basic validity. This synopsis made his book *The Integrative Action of the Nervous System* (1906) a milestone in neurophysiology, which has been compared 'in importance with Harvey's' 300 years older '*De motu cordis* in marking a turning point in the history of physiological thought' (Fulton, 1952, p. 174). For Sherrington, spinal reflexes did not have a 'purpose' but a 'meaning.' He replaced the formerly presumed 'soul' of the spinal cord (e.g., Legallois, 1812; Pflüger, 1853) as the driving force for reflexes and even voluntary movements by an astonishing exactly considered function of spinal interneuronal activity. He replaced the Cartesian reflex behaviorist view by the still-relevant view that the performance of coordinated movements as a basis for animal and 'conscious' human behavior requires an integration of 'intrinsically' generated brain functions with 'extrinsically' induced reflex functions. In this context he suggested that the pure 'apsychical' reflex behavior without a contribution of 'mind' loses in importance with phylogenetic ascendance, playing the smallest role in man: "The spinal man is more crippled than is the spinal frog" (Sherrington, 1906/1947, Foreword, p. xiv).

As a true scientist Sherrington never felt that he had arrived at any incontrovertible truth and in a typically unpretentious understatement he concluded: "I have dealt very imperfectly with a small bit of a large problem.... The smallness of the fragment is disappointing" (1931 p. 27); this a statement from a man about whom Frederick George Donnan wrote in 1921 to the Nobel Committee: "In the field of physiology and medicine, Professor Sherrington's works remind one of that of Kepler, Copernicus and Newton in the field of mechanics and gravitation" (in Schuck et al., 1962, p. 310).

The Philosopher

Like for example, Descartes before and Eccles after him, Sherrington realized that mere experimental investigation of the nervous system was not sufficient to solve the fundamental problem of the body/brain–mind relation, particularly the difficulty of explaining how it actually works. In the Rede Lecture on *The Brain and its Mechanism* (Sherrington, 1933) in which he considered the complexity of the brain functions in motor control and behavior and in which he tentatively approached this problem, Sherrington took a fully dualistic view. He even negated any scientific right to "conjoin mental experience with the physiological.... The two ... seem to remain disparate and disconnected" (1933, pp 22–23).

But later in the Gifford Lectures, which he held in Edinburgh in 1937–38 (published as *Man on his Nature* in Sherrington, 1940 and as an extensively revised new edition in 1951) he took up the great enigma of the brain–mind relation in the light of his new neuroscientific knowledge. Rejecting the assumption of a mysterious mind of a 'heavenly' origin he stated, "Ours is an earthly mind which fits our earthly body" (Sherrington, 1940, p. 164). 'Mind' for Sherrington was coupled to motor acts, 'mind' only being recognizable via motor acts. He suggested that 'mind' is graduable, that a recognizable 'mind' is developing in the developing brain in humans and to varying degrees in animals. Regarding the relation between the two concepts of 'energy' (assuming 'matter' also as 'energy' in the physical sense) and 'mind', he concluded that 'mind' as a function of the living brain is mortal, while the 'energy' the matter – is immortal, just changing its state when the brain is dying. In his discussions he entirely avoided the complicating

problem of an 'immortal soul', which he, as being himself oriented towards Natural Religion, left to the Revealed Religions: "When on the other hand the mind-concept is so applied as to insert into the human individual an immortal soul, again a trespass is committed" (Sherrington, 1940, p. 355).

When Sherrington with something like resignation stated, "But the problem of how that [body-mind] liaison is effected remains unsolved; it remains where Aristotle left it more than 2000 years ago" (Sherrington, 1906/1947, Foreword, p. xxiii) he probably underestimated the contribution of his step towards the direction of a solution by defining 'mind' as a function of the brain requiring a complex integrative action of the nervous system; a view which was taken up and further developed by one of his students, Sir John C. Eccles (1970, Eccles and Gibson, 1979).

And Now?

As stated in the section 'The Philosopher' the experimentally well-based theories and concepts, which Sherrington had creatively developed with great visionary imagination, formed a well-recognized secure foundation for future developments in the neurosciences.

The half-century after Sherrington's death has brought an immense increase in neuroscientific knowledge. First, particularly, the technique of microrecordings from nerve cells and the analysis of ionic membrane mechanisms confirmed and extended the knowledge and hypotheses based on Sherrington's activities on brain and spinal functions in sensory perception, motor control, and behavior. Then new techniques allowed for analytic investigation of more and more detailed neuronal structures, functions, and interactions down to the molecular level. New gentechnical approaches enabled the 'production' of innumerable variants of mice with defined genetic defects at the molecular level.

However, the bewildering mass of results originating from these experiments opened up a host of new questions. What is required now is a new 'Sherringtonian' approach which comprises a complex critical analysis of today's entire neuroscientific knowledge (from molecular mechanisms up to the level to complex behavior) in an integrative synopsis and which develops new concepts to explain the sophisticated brain functions and their relation to mind as expressed by behavior. Despite the exponential increase in detailed neuroscientific knowledge, we have not really come closer to a solution of that problem since Sherrington.

Abstract

Edward Shils was a prominent American sociologist and social theorist who spent much of his career in Britain. He was the translator of Karl Mannheim and collaborator with Talcott Parsons. His own social theory concentrated on the relation of primary groups and intellectuals to the center of society, which he conceived of in terms of its charismatic character. Unlike Parsons, he was especially concerned with the conflicts between the social attachments of people, and especially with those involving the transcendental. These conflicts were the basis of his account of intellectuals and their response to their own society.

Edward Albert Shils was born in Massachusetts on 1 July 1910 and died in Chicago on 23 January 1995. His father was a Russian Jewish immigrant, a cigar maker, and an employer. His mother was born in Pennsylvania. Neither was educated beyond the eighth grade. The family name was originally Shilo, a variant of a Hebrew word meaning 'his gift.' Shils, having grown up in Philadelphia, attended the University of Pennsylvania, graduating in 1932, having majored in French literature. He trained as a social worker at the New York School of Social Work, and was employed as a social worker during his training, in Chicago. In Chicago, he became involved with the sociologist Louis Wirth, with whom he studied German sociological theory. He was also involved with the economist Frank Knight, who had done the first translation of Weber into English, *General Economic History* (1927), taking a seminar on Weber's *Wirtschaft und Gesellschaft* organized by Knight. Shils also translated other works by Weber (and Simmel) that circulated among students. These eventually became the basis for the translation of three of Weber's most important methodological essays, *Max Weber on the Methodology of the Social Sciences* (1949). During the 1930s, Shils was employed on grants and spent a year at Columbia, before being appointed to the teaching staff of the (Undergraduate) College of the University of Chicago.

He played a central role at The University of Chicago in the development of the famous sequence of social science courses that were part of the general education of undergraduates, and during the 1940s recruited an especially distinguished set of teachers for them, including David Reisman, Barrington Moore, and Sylvia Thrupp. He was especially involved in an advanced course called Freedom and Order, which dealt with the more philosophical aspects of social science.

During the war, Shils, while in England, along with Morris Janowitz, interrogated captured U-boat crew. Out of these interrogations emerged his study of the social relation of small army units as primary groups, without very little, if any, ideological underpinnings. Shils was appointed for part of the year to the London School of Economics in 1946, and was appointed in 1947 to the Committee on Social Thought, and continued in this capacity until his death. From this period to his death, he held joint appointments at the University of Chicago and several universities in England, in particular at the Cambridge University.

Shils wrote in a variety of fields, most of which he came to out of personal acquaintance. At the London School of Economics, he was exposed to the students of the Colonial Empire, notably India. This led to a long engagement with Indian intellectuals and his monograph *The Intellectual between Tradition and Modernity: The Indian Situation* (1961a), and in the 1950s to participation in the New Nations project at the University of Chicago. In the late 1940s, he was appointed to a committee of scientists concerned with the atomic bomb. This led to a long-term engagement with science and science policy, and to his book *The Torment of Secrecy* (1956). His relation with Michael Polanyi, beginning in 1946, led him to a distinctive interest in the social nature of science, to involvement in the Congress for Cultural Freedom, and ultimately in 1962 to the founding of the journal *Minerva*, which drew many of its contributors, especially in the early years, from the participants in the struggle against the Marxian picture of science.

Although Shils was an intellectuals' intellectual, with broad and penetrating engagement in many different scholarly areas, he was not a 'public intellectual' in the conventional sense. Nonetheless, he received many public honors, including the Jefferson Lecturer in 1979 and the Balzan Prize in 1983. He was intensely and personally engaged with leading intellectuals, scientists, and literary figures throughout the world. He was an important behind-the-scenes participant in the *Bulletin of Atomic Scientist* and the journal *Encounter*, and played a large role in *The American Scholar*, as a board member. At dinner in his home, one might find at the table scholars like Arnaldo Momigliano, Owen Chadwick, Hugh Trevor-Roper, the sinologist Michael Loewe, or Wolfgang Mommsen. He was a close friend of Raymond Aron and of the novelist Dan Jacobson and Nobel Laureates Saul Bellow and V.S. Naipaul, and a champion of the Indian author Narit Chaudhari. He brought Bellow to the Committee on Social Thought at the University of Chicago, and Bellow drew on his persona to create some of his most memorable characters. Despite the fact that he lived in this rarified atmosphere both in Cambridge and Chicago, he had a strong sense of empathy with ordinary people, tradesmen, and shopkeepers, and was highly sensitive to their attempts to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61284-9

be respectable and honorable in their dealings with others. This sensitivity can be seen in his published scholarly work, for example, in his humanistic understanding of the *Calling of Sociology* (1961b) and the collection of his articles published under the title *The Constitution of Society* (1972).

Early Writings

Shils differed from his contemporaries Talcott Parsons and Robert Merton in being equally immersed in both the intellectual traditions of American sociology, through his experiences at Chicago, and European sociology. Shils was a great admirer of Robert E. Park and took courses, including one from Ernest Burgess based on the famous Green Bible, Park and Burgess' *Introduction to the Science of Sociology* (1921). He was a student in Park's last seminar in the department, on Collective Behavior. The main line of his intellectual development, and the beginnings of his own distinctive picture of society, came from Charles Horton Cooley and the idea of the primary group. Nevertheless, his thorough study of European thinkers and their intellectual traditions extended his initial concerns radically and in novel directions. His mentor in the 1930s was Louis Wirth, who employed him on a project dealing with the German theorists of the methodological foundations of sociology, and he also worked on a study of the occupational structure of Chicago. At the same time, however, he came into close contact with the economist Frank Knight, who was an admirer of Max Weber. He also became acquainted with Alexander von Schelting, a German refugee who had written a study of Weber's concept of ideal types. Through Knight's seminar on Weber, he became an avid reader of Weber and an active participant in the project of translating Weber, not only the latter's methodological essays but also, along with Max Rheinstein, Weber's writings on law from *Wirtschaft und Gesellschaft* (1954). Through Wirth he became the cotranslator of Mannheim's *Ideology and Utopia* (1936) and the translator of Mannheim's *Man and Society in an Age of Reconstruction* (1940). His career was also helped by the notice of Robert Hutchins, the controversial and charismatic president of the University of Chicago.

In the early 1940s, he served in the US intelligence services (the Office of Strategic Services, predecessor to the Central Intelligence Agency), in England, where he became personally acquainted with Karl Mannheim. He was also exposed to a new strand of thought, which was developing in response to the ideologies that played a role before and during the war. In part, this strand reflected the problem of defining the aims of the war; in part, it represented the attempt by liberal refugees from central Europe to articulate a response to fascism and communism in the nonideological English context. In the course of the decade, Shils became associated with the London School of Economics, establishing relations with Popper, Hayek, Polanyi, and T.S. Eliot, and became aware of the work of Michael Oakeshott. He had already expressed skepticism over Mannheim's views on planning. In London, he also became aware of the issues over the 'planning of science' and freedom of inquiry in science that later occupied much of his time and effort through his editorship of the journal *Minerva*.

His formative experience as an independent researcher was his wartime studies of captured Wehrmacht soldiers and deserters, who were being interviewed to discover the sources of unit cohesion. In the paper *Cohesion and Disintegration of the Wehrmacht in World War II* (1948), published with Morris Janowitz, Shils argued that personal bonds between unit members, not ideology or loyalty to Hitler, accounted for cohesion. Shils later extended the insights of this research in the paper *Primary Groups in the American Army* (1950).

This research, involving the relation between ideology and personal relations, pointed toward a preliminary understanding of society that Shils was later to elaborate in several directions. The conclusion to the cohesion paper was that most men are members of the larger society by means of identifications, which are mediated through the human beings with whom they have personal relations. What was still obscure to him was what these identifications with the larger society were and how they worked. Nevertheless, the model had some significant negative implications. Primary group bonds were critical to the emotional life of people and to their sense of Weness. Ideology was not what held groups together on its own. The "limited capacity of many human beings to sustain a direct, continuous, and intense relationship to the center of their society" ruled out such models of society (1975: p. xxvi). It was also true that some people were sensitive to ideology, to the pull of larger units or ideas, and others had primary group connections with these people, and this could be a formidable source of cohesiveness. Or an ideological movement could fail for the same reason – the inability to develop primary group bonds.

In the study of the Wehrmacht, Shils also discusses themes that become prominent later, including the content of the primary group relations themselves, notably, in the case of the German army, the overwhelming emphasis on honor. He also shows a strong interest in the relation of personality structure and the capacity for different kinds of primary group relations. In this case, discipline and the values and psychological inclinations of Germans of the era fit well with and facilitated unit cohesion. This reasoning reflected the interest in psychoanalysis of Harold Lasswell. The issue reappears in his thorough criticism (1954) of *The Authoritarian Personality* (Adorno et al., 1950).

Shils followed this publication with a consequential collaboration with Talcott Parsons on the nature of values and norms, a definitional enterprise still cited in the interdisciplinary literature on norms. This association marked Shils professionally in the minds of sociologists as a 'Parsonsian.' This association was a double-edged sword: it placed Shils in a position of centrality in academic sociology, but obscured his own originality, and exposed him to the strong negative reaction to Parsons that came to define much discussion of 'sociological theory' over the next two decades. But Shils, who respected Parsons personally, and initially regarded *The General Theory of Action* (Parsons and Shils, 1951) on which they collaborated as an advance, soon became dissatisfied with Parsons' penchant for abstract classificatory schemes, and returned to the elaboration of his own understanding of society.

The collaboration with Parsons had pointed to the lacuna in his own understanding: a sense of what it was that people who

identified with the larger society were identifying with, and what modes of identification existed. His fascination with the question of what binds people was expressed again shortly in his study of the meaning of the coronation of Queen Elizabeth II in 1953, which took his thinking in another direction. Shils had been impressed with Rudolph Otto's *The Idea of the Holy* (1923), Anders Nygren's *Agape and Eros* (1953), and with Weber's ideas about charisma. Shils had a long history of skepticism about the idea that societies were held together by ideology. The Coronation pointed to a different kind of tie, different as well from the primary group.

Shils attempted to resolve the muddle of what kinds of tie held societies together in various ways, in unpublished papers. But despite spending much of his thought on the problem, and operating with a general picture of society, Shils was never entirely happy with his formulations, and never published a comprehensive 'theory of society' that articulated this picture. He was fascinated with the deviations from the core model: the fact that intellectuals, for example, were typically alienated from and often hostile to the central institutions of their own societies. He was also involved in the study of the patched-together 'New Nations' that were emerging out of decolonization, whose states lacked the central institutional status in relation to other social ties characteristic of European nation states, and were often led by intellectuals oriented to Europe.

The key ideas eventually emerged in an incomplete form in *Primordial, Personal, Sacred, and Civil Ties* (1957), where Shils reiterated the negative implications of his understanding that "modern society is no lonely crowd, no horde of refugees from freedom. It is no *Gesellschaft*, soulless, egotistical, loveless, faithless, utterly impersonal and lacking in any integrative forces other than interest or coercion" (1957: p. 112). But his argument also implied that neither is it a Parsonsian system governed by internalized norms nor an all-pervading culture: "the cultural value or belief system of a society can be lived up to only partially, intermittently, and only in an approximate way" (1957: p. 111). The pull of other demands and needs prevents it; immediate needs and authorities are more important.

Shils often wrote about his thought in an autobiographical way. He described "Primordial, Personal, Sacred, and Civil Ties" as a "rambling tale of my intellectual wanderings." This was never intended as a summary of his theoretical image of society, but it comes closest to being one: he mentions a manuscript 'Love, Belief, Civility,' which was intended to be his contribution to an understanding of "the bonds which hold a society together" (1957: p. 112). The book, which would have contained his own 'theory of society,' never appeared. The core of this project was a puzzle inherited from Cooley. Cooley assumed that the ethos of the primary group could be adopted as the ethos of the public life of the larger society; Tönnies contrasted the two and generally regarded them as irreconcilable. Shils turned to Weber to resolve the conflict by extending the notion of charisma. Weber intimated. Shils thought that charisma was at the base of rational legal authority. And this intimation could be generalized to make sense of the different attachments of people not only to their primary group but also to the central institutions of modern society and to ultimate values. Mayo saw that the functioning of corporate bodies depended on the functioning of primary groups. And this fit with Shils own observations of the military, and of ideological groups. In each case, there was a special significance of linking persons with a special degree of attunement to central institutions and ultimate values, who connected the enthusiasm of the primary group with the corporate body.

This basic insight remained with him, but he recognized that it did not differentiate sufficiently between types of ties between people and between forms of attachment to such things as sacred objects, ultimate values, and collective identities. He also recognized the need for a better understanding of collective life, which he could now formulate in terms of 'centers' and 'peripheries.' In the 1950s, he wrote about this in a way that was congruent with the Parsonsian doctrine of the central value system of a society. But Shils was even then construing this in terms of the sacred and charismatic character of central institutions and the values they represented.

Unlike Parsons, Shils was sensitive to the conflicts that arose between various attachments, and especially to the way in which intellectuals appeared to be hostile to the governing institutions and values of their own societies. This phenomenon became a major theoretical focus for him, as he attempted to incorporate both contrasts and attachments within his understanding of center and periphery.

This basic structure of the relation of primary groups to higher things was an unchanging and unambiguous feature of Shils' image of society. A more elusive aspect was his account of the higher things themselves, exemplified by his idea that every society has a center and a periphery that is oriented in some sense to that center, but often in sporadic and negative ways. At some times, Shils comes close to the Parsonsian dogma that society is held together by the existence of a central value system. But Shils discussed the issues of consensus in ways that both extended this idea and conflicted with it. What preoccupied Shils, for most of his work, were cases in which orientations conflicted with one another, and traditions that operated largely independently of the central traditions of a society, such as the tradition of science. In the case of intellectuals, the conflict between their orientation to transcendent ideals and the prosaic, compromise-filled practices of getting and spending of everyday life was the source of their rejection of their own societies.

Shils was particularly fascinated with intellectuals in the developing world, whom he encountered in great numbers at the London School of Economics and during his many trips to India. And the comparison between Western polities and the 'New Nations' overlaid on old societies that had been produced by decolonization sharpened his views of intellectuals, who were torn between their sense of ownership of their own societies, their ambivalence toward traditional culture and their yearning for a deeper connection to it, their attachment to 'aboard' the traditions of oppositional politics, and in the many cases of underemployed intellectuals, by their exclusion from power and desire to exercise it. Each of these attachments can be understood as an orientation to a center, but the orientations conflicted, leading to disappointment and an attraction to ideological critique.

At the theoretical level, Shils gradually came to understand these attachments in terms of the sacred and charisma. Controversially, he radicalized Weber's notion of charisma to apply not only to central institutions but also to anything with

an element of transcendence or superiority, including power itself. This allowed him to account for the myriad tensions between the center of a society and that society's peripheries. It also allowed him to assimilate a great deal of conventional sociology, such as studies of occupational prestige, into the basic picture. The vicissitudes of the center and of the charisma of various transcendent objects were means of accounting for such things as the decline of deference and the long historical rise of egalitarianism, which could be seen as a transfer of charisma to the individual.

This evolving image of society went far beyond notions of consensus, and Shils in his retrospective writing dissociated himself from the emphasis on consensus, noting that in the 1930s he had been skeptical of the idea, accepted by many of his contemporaries impressed by the apparent successes of communism and fascism, that modern societies needed an integrating ideology. But he was also responding to events: he considered the period of the 1950s in the United States to have involved a high level of societal consensus. His experience of the conflict over the war in Vietnam and the vociferous response to Nixon led him to conclude that this consensus was broken.

Shils continually struggled with the question of what and how the center, collectivity, and society should be understood. He inherited from Knight and Weber a strong skepticism about collective concepts. But he was equally skeptical about the reduction to individual rationality, which he regarded as Hobbism, as is clear from his book *Tradition* (1981). We-ness was, he thought, a genuine phenomenon, but also a mysterious one. He also believed in the existence of a realm of "symbolic constructions which depict the ultimate nature of things" (1997a: p. 202) toward which intellectual life was oriented. Reconciling these commitments was not only difficult: perhaps it was impossible. But as a guide to the conflicting commitments characteristic of social life itself, it enabled Shils to identify the grounds for such apparently anomalous phenomenon as the hatred of intellectuals for their own societies and the attractions of ideology.

Shils saw the rise of ideological politics and the rise of a category of intellectuals free from dependence on patronage as closely linked. But he saw that the ideological impulse itself arose from among the same sources as social consensus, namely, an orientation to sacred central things – and in particular, in the West, to the Judaic–Christian tradition itself, with its strong appeal to the notion of justice and its correlated sense of the injustice of the earthly order. This common heritage facilitated Millenarianism and often a Manichaenism that provided a focus for a sense of grievance and injustice. Intellectuals, by virtue of their own traditions and the fact that they were not responsible for the practical realities of decision, were free to indulge in criticism of the established order in light of these grievances, and to construct intellectual justifications for their grievances.

In *Ideology and Civility* (1958), Shils, paralleling such related thinkers as Michael Oakeshott, contrasted ideological politics to the mundane politics of civility. The latter was a politics limited by the sense of the possible, by a respect for the different opinions of others, by the recognition that the achievement of one good is normally linked to negative consequences for other goods and that virtue is not realized solely in one form, and by a respect for the limits of authority and power. But the balances of this kind of politics were difficult to maintain, especially under the pressure of ideological movements that did not respect these balances. In particular, the intrinsic conflicts between the collective and individualistic forms of liberalism are difficult to balance.

Shils also wrote extensively on issues that grew out of the atomic movement, on science, and on cultural issues, notably the issues of mass culture that excited commenters on the Left during the postwar period. These writings were responses, sometimes polemical, to particular intrusions of ideology into scholarship or social science, or literary criticism. The period from the end of World War II to the early 1960s during which most of these writings were published was particularly fraught, with former communists and liberals responding to the hard Left on the issues of the day, very often in the form of literary and cultural rather than overtly political arguments.

Shils had, from the 1930s, an interest in Left-wing movements, had discussions with communists at the University of Chicago, and was well-informed about ideological matters. He was not tempted himself, as many of his contemporaries were, and was critical from the beginning of the naiveté of Mannheim about the implementation of social 'plans,' a skepticism he explicitly linked to Frank Knight. After the war, he was acutely sensitive to the influence of the Stalinist Left over intellectuals. At the same time, his involvement in the Atomic Scientists movement, and earlier in peace movements, placed him far from the 'right.' He appreciated the saying that the only serious politics was conservative liberalism and liberal conservatism. His political views were similar to those of his friend, the sociologist Raymond Aron.

The experience of the student movement in the late 1960s and the early 1970s and the debates over the war in Vietnam as well as the divisive politics associated with the Nixon Presidency altered Shils views and his intellectual direction. He sensed that the consensual character of American society of the 1950s had permanently changed. While insisting that there be no toleration for the disruption of the university, he, nevertheless, advocated, in private advice to the President of the University, Edward Levi, lenience toward students involved in disciplinary proceedings related to the protests over the war. But he also took the view that the academic ethic itself was under grave threat. He published originally in Minerva a translation of Weber's writings on the subject, "Max Weber on Universities: The Power of the State and the Dignity of the Academic Calling in Imperial Germany" (1974), and wrote, as a member of the International Council on the Future of the University, *The Academic Ethic* (1974) as an attempt to define this ethic and identify the challenges to it.

The bulk of his later writing, after 1976, concerned the university, intellectuals, and memoirs of the great scholars whom he had known. He also edited volumes on Cambridge women academics and on the scholars of The University of Chicago, in an attempt to record the personal side of these communities and describe the character of great scholars who had fulfilled the academic ethic. His own recollections of individual scholars form an important part of the historical record of the intellectual life of the twentieth century, and are an important contribution to the genre. Three posthumous collections of his later writings capture well the intellectual preoccupations of this remarkable person and scholar for the

period after the earlier publication of those three volumes of his collected papers: *The Intellectuals and the Powers* (1972), *Center and Periphery* (1975), and *The Calling of Sociology* (1980). To those volumes of his collected papers should be added *Tradition* (1983). The three posthumous collections are *The Calling of Education* (1997a), which brings together Shils' reflections on the academic ethic, the character of the modern university, and his important Jefferson Lectures of 1979; *The Virtue of Civility* (1997b), which contains his later reflections on the constitution of modern society; and *A Fragment of a Sociological Autobiography* (2006), which revolves around Shils' reflections on the path of his intellectual preoccupations throughout his life.

Shklar, Judith N (1928–92)

Andreas Hess, School of Sociology, University College Dublin, Dublin, Ireland

Abstract

Judith Shklar's political theory defies traditional labels. It emerged, as one observer has pointed out, between the 'end of ideology' discussions of the 1950s and the early 1990s discussion of the 'end of history.' Shklar's writings contributed significantly to modernizing political thought by arguing for a new, more skeptical, and stripped-down version of liberalism that brings political theory and real-life experiences closer together.

The Formative Years (1928–50)

Judith Shklar was born Yudita Nisse in 1928 in the Latvian capital of Riga. Her parents belonged to the wealthy Jewish elite of the city. They were not religious, which meant that for the children a modern French-style education was favored, including the teaching of classical and modern languages, literature, and the sciences. Additionally, private education continued at home.

By 1939 Riga began to look more and more like a trap. The Nisse family escaped to Sweden in a lucky moment just before the Hitler–Stalin pact, which led first to the Russian occupation of Latvia, followed by the German invasion of Latvia a few months later. However, Sweden did not look too safe either after the Nazi's occupation of neighboring Norway. The Nisse family realized that in case of a Nazi invasion they would not be safe from persecution, arrest, or deportation. Equipped with false papers they escaped via the Soviet Union and Japan to North America. On arrival in Seattle, the family was first detained as illegal aliens but eventually discovered by a Rabbi who had inspected the camp. After their release, the family finally settled in Montreal.

Judith perfected her English reading and writing skills while attending a Protestant School. Later, at McGill University she encountered a gifted teacher, Frederick Watkins, an American Rousseau specialist who was to become her supervisor. Watkins was so impressed with the intellectual abilities of his student that he recommended her to Harvard. In 1950, together with her newly wed partner Gerald Shklar, Judith moved to Cambridge, Massachusetts near Boston.

In the Aftermath of Totalitarianism (1950–64)

At Harvard, the German-American scholar Carl Joachim Friedrich (1901–84) became Shklar's supervisor and mentor. Friedrich, who taught comparative politics, showed Shklar the ropes; he gave her space and the opportunity to develop her own teaching and research profile.

Shklar found herself falling between several stools. She was too young to belong to the group of German émigré scholars that had begun to take hold in institutions of higher learning; at the same time she did not fully belong to the established Harvard crowd either. She discovered that she was a particular kind of refugee and therefore somewhat of an outsider – an insight that stayed with her for the rest of her life and that would have a decisive impact in the development of her political theory. As an 'exile from exile' Shklar would remain a lifelong skeptic. She consistently questioned the repository of wisdom of the Western humanist canon and its underlying sense of human progress and improvement. Having faced the totalitarian threat herself she also had trouble understanding the common intellectual treatment of Fascism and the Western liberals' tolerance for Stalin.

Shklar's interests leaned to the study of modern ideologies rather than to a formally oriented comparative politics in the way that her supervisor Friedrich promoted it. For her thesis she opted for a topic that sounded very Hannah Arendt-like in theme and scope. The original intention had been to discuss the Holocaust and the limits of understanding and explaining the incomprehensible and the constraints this imposes for the development of modern political theory. For her thesis, entitled 'Fate and Futility: Two Themes in Contemporary Political Theory' (unpublished PhD, Radcliffe, 1955), Shklar was awarded Harvard's Radcliffe Prize and the Birkhead Prize of the American Political Science Association.

Shklar's first book, *After Utopia*, was a revised version of the PhD dissertation (Shklar, 1957). The book's stated aim was to assess the state of contemporary political theory and political philosophy after the extreme experiences of totalitarianism and the Second World War. Like Arendt, Shklar observed a theoretical *stasis*; yet in contrast to Arendt's melancholia for the classics, Shklar argued for a fresh start and an altogether more rational attempt at political theoretical conceptualization. She saw a need for more realism in political theory at a time when an old-fashioned liberalism had "become unsure of its moral basis, as well as increasingly defensive and conservative" (Shklar, 1957: p. viii). Her critical remarks were not only directed at Cold War liberals but also directed at Friedrich and Arendt who continued to repeat the mantra of totalitarianism almost *ad nauseam* but who seemed unable to explain what liberal democracy and political theory could actively do in order to become more attractive and convincing, particularly in light of the ideological competition.

In 1963 the question of tenure came up. After years of teaching and after some promising publications, documented through a prize-winning dissertation, a book with Princeton University Press, a second book soon to be published with Harvard University Press, and being the recipient of a Guggenheim fellowship Shklar could simply not understand why the Department was leaving her dangling. In the end Shklar, who was financially independent, decided to ask the university

whether the process could be short-cut by offering her a permanent half-time lectureship instead. The University agreed and in 1963 Shklar was finally offered employment as a lecturer, a peculiar arrangement that would last as late as 1970.

Shklar's second book, *Legalism*, appeared in 1964. Between the so-called Hart–Fuller debate of the late 1950s, which discussed the role of legal positivism in the context of the Nuremberg Trials, and the discussion surrounding Arendt's *Eichmann in Jerusalem*, it seemed well placed. An analysis of the trials provided an opportunity to discuss the relationship between law, morality, and politics. More specifically, Shklar argued that formalized justice should not be regarded as an end in itself but also that just procedures cannot create a democratic order on its own. This had been the illusion of the judges in Nuremberg: if only the laws were seen to be operating, the impression of functioning democratic institutions and politics would follow from that. Against such assumptions Shklar argued that it was a legalistic illusion to think that in the end the example of the Nuremberg Trials could actually prescribe some future international criminal law and court system: "The trial was a tribute both to the intellectual limitations of legalism as an ideology and to the real political value which legalism has in practice" (p. 147).

Shklar points out that it was true that the trials took place in a legal vacuum. There was no properly functioning system of international criminal law. In this context it was a sense of justice that turned out to be the main driving force behind the trials. This was very much against the notion of positive law that maintains the distinction between legal procedures and political aims and values such as justice. What has happened then was that the new crimes committed and the trials conducted in response to barbaric deeds had led to an interpretation that tried to put together again what had in reality become separated. Put differently, after the experience of totalitarianism, it became harder to suggest that legal procedures, justice, and politics were not linked at all.

The Making of a Political Theorist (1964–86)

Shklar's next book, *Men and Citizens*, was on Rousseau (Shklar, 1969). The study of the Genevan philosopher was not that far removed from her earlier concerns and epistemological interests as it might appear on first sight. Engaging with Rousseau could not only lead to a critique of classic liberalism, but *ex negativo* his arguments touched on a number of themes that, according to Shklar, went to the very heart of a critical theory of liberalism – something that students who saw Rousseau only as an intellectual precursor to Marx seemed to have forgotten.

Shklar observed that for Rousseau utopia served foremost as a critique of both religious notions and contemporary society; utopias were practical orientation points: they educate the senses and guide judgment. At the same time Rousseau knew that a simple return to nature or past utopias was impossible. Once mankind had embraced the division of labor, including developed forms of property structures and inequalities, there was no turning back. Utopian idylls like Sparta and the tranquil rural Swiss home only confirmed that mankind was on a restless search, driven to find a home to rest, while actually being unable to encounter one in reality.

According to Shklar, Rousseau had learned his psychology, his 'history of the human heart,' mainly from Locke. The genetic method freed him from having to deal with actualities or real historical facts. The method consisted of the description of a civilizational drama, which has to be understood as a kind of repeated *ur*-condition, acted out time and time again. However, while man was responsible for maintaining and prolonging the situation, he had arrived at this situation innocently. The societal chains were there first: man, although born equal, had to deal with inequality and constraints from the very beginnings of the civilizing process.

In order to fully reveal his human potential, for Rousseau certain 'psychological' capacities in man have to exist: the ability to make choices, the use of imagination, memory, the capacity of self-perfection, and the ability to feel pity at the sight of human suffering. The human mind appeared thus to be in a permanent struggle: on one side we find these positive psychological capacities and on the other side the social and identifiable constraints – the tension that results in human suffering. Only deep introspection and insightful self-education, including searching for one's freedom by physical travel, provided an escape.

The final part of Shklar's study was devoted to Rousseau's idiosyncratic use of language and style. It was the French philosopher's 'organizing images' that explained in large part his popularity and success. Rousseau had the advantage of having been a thinker who, unlike many modern academic theorists, was never confined to narrow specialisms. His language was thus far removed from abstraction without ever considering academic jargon.

Shklar's *Men and Citizens* contained a scarcely veiled self-critique. In *After Utopia* Shklar had pronounced modern political theory to be in deep crisis. With Rousseau, Shklar showed that political theory, rightly conceived, might provide a way out. It connected the past to the present and, if studied and practised carefully, could reveal a 'surplus meaning.' Shklar had demonstrated that Rousseau had discussed all the ingredients that modern political theory was concerned with, in particular the theme of justice and the concomitant need to avoid extreme inequality. His philosophy could be used to show the continuous relevance of modern republican ideas and themes such as the formative experiences of individuals as expressed in virtues and vices, ideas that remained also important to liberal thought. Furthermore, an engagement with Rousseau's philosophy could help us to think about the appropriate body politic and those governmental structures that would guarantee freedom from fear and cruelty.

As with Rousseau, the preoccupation with Hegel derived from preparing and teaching a core course on the Enlightenment at Harvard. *Freedom and Independence* (Shklar, 1976) was a critical analysis of Hegel's phenomenology. For Shklar, Hegel merged not only aspects of passion and reason, he was also the first philosopher to consider the idea that the progress of human thought could be explained by systematically studying social interaction. The analysis of conflict between the individual and his social and natural environment, and how thought emerged from that confrontation, remains his greatest contribution. What emerges is, according to Shklar, a common concern for how individual and social environment are linked and how they interacted. As to his speculations about how to

solve the problem, however, Shklar was less sure. Hegel had little time for Rousseau's educational suggestions, while Rousseau would certainly have objected to the achievements and advantages of *Bildung* as described by Hegel. Hegel's reservations *vis-à-vis* Montesquieu were of a different kind: Hegel accepted the latter's distinctions between the ancients and the moderns; however, the real distinction between the two, according to Shklar, was that Montesquieu clearly favored reform and the proper functioning of political institutions based on honor and decent behavior while Hegel favored a change of mind and morals, a different 'spirit.'

While Shklar remained unimpressed by the Prussian's attempt to explain the intellectual foundations on which modern civil society could be built, there were still some important insights to be gained from interpreting the text in a different way by reading it as a kind of political psychology. Most critics seem to have agreed with Shklar. George Kateb praised and singled out Shklar's interpretation of Hegel's moral concerns and the weight she gave to the philosopher's discussion of cultural, political, and social ingredients that are necessary to establish a moral community (Kateb, 1987). Equally the Hegel expert Z.A. Pelczynski stressed Shklar's dissection of the political-cultural dimensions, such as the moral costume and the critical self-reflection, necessary to maintain a modern political system (Pelczynski, 1977).

After having been employed as a lecturer for many years, Shklar's status, like that of a dozen other women at Harvard came under scrutiny. A critical internal report had been filed, which was soon followed by swift action by the university; it led finally to the promotion of those female Harvard members of staff who had been denied tenure until then – Judith Shklar being one of them. More recognition followed. Shklar was elected to President of the American Society for Political and Legal Philosophy in 1982, and in 1983 she became Vice-President of the American Political Science Association. The same year Shklar spend half a year as Visiting Fellow at All Souls in Oxford. This was followed by a year as Pitt Professor of American History and Institutions at Cambridge University.

Shklar's own experience of the threat of totalitarianism and fear had made it difficult for her to continue pursuing political theory in a business-as-usual fashion; for her the time for great systems, ideas, and theorems was over. What was needed was to reflect about problems in a way that would pay its dues to the extreme experiences of the century but at the same time acknowledge that the world had not just suddenly come to a halt. Shklar was most interested in those formative processes that used to be the theme of classical republican thought. However, she also realized that what was needed was to re-think the old themes of vices and virtues in the context of modern liberal democracy. Shklar's declared aim was to bring political theory closer to the social and political realities of modern society by discussing modern vices not just in the political context but in the social realm as well. This was not easy, particularly since the boundaries between the spheres always shifted.

In *Ordinary Vices*, Shklar argued that in contrast to other liberal conceptions who aim at a *summum bonum*, what she termed the modern and specifically American imprinted 'liberalism of fear,' refers only to a *summum malum* – cruelty (and, in response to cruelty, how to avoid suffering) (Shklar, 1984: p. 7ff). The other vices (hypocrisy, snobbery, arrogance, betrayal, and misanthropy) need to be ranked in relation to the first, cruelty. Shklar further maintained that there were many aspects to vices and to conceive them simply in either simple affirmative or negative terms would not do justice to the complexity of the problem. Hypocrisy, for instance, may, generally speaking, not be well regarded. Yet it allows people to pretend to be better than they are and it would therefore be highly problematic for a liberal democracy to take public measures to abolish it. A similar argument could be made in the case of snobbery, which is hardly a crime, let alone always necessarily an antidemocratic attitude. Treason and betrayal seem to be more problematic; yet again, no one-size-fits-all solution can serve as a response to the complexity of these two vices. What one person sees as treason to the fatherland, another person might see as a positive contribution or even regard as the truly sane response to cruelty (resistance to totalitarian regimes comes to mind here immediately). Adultery, another example of betrayal, can occur between married or unmarried partners and often does destroy confidence. However, a private breach of trust does not necessarily mean that trusting relationships with other people are impossible. Even misanthropy does not always have to have negative consequences. It may merely be a personal protest against the brutal way the world sometimes works. It might even have some positive effects as Shklar illustrates by referring to examples from Shakespeare to Swift.

Looking at the various vices nothing justified putting cruelty first more than the experiences of the twentieth century. As a consequence "liberal democracy becomes more a recipe for survival than a project for the perfectibility of mankind" (p. 4). In other words, liberalism should not be seen as an "amoral free-for-all" but rather as a defense of a delicate achievement in which we continue to "endure contradiction, complexity, diversity, and the risks of freedom" (p. 5).

As Patrick Riley, a former student of Shklar, noted, *Ordinary Vices* was "the *summa* of Shklarism," "a fusion of psychological confidence and moral scepticism" (Riley in Memorial Brochure, 1992: p. 102). In an earlier review, Riley had already commended Shklar for having written a "brilliant, psychologically insightful, and deeply humane book … In it Montaigne and Hegel meet to wonderful effect: Montaigne supplies the 'ordinary vices'… and Hegel brings the method of illumination" (Riley, 1985: p. 610).

Ordinary Vices had been inspired by Montaigne, but Montesquieu was never far off Shklar's intellectual radar screen. In a monograph for Oxford University Press's series 'Past Masters' she took the opportunity to put forward her interpretation of Montesquieu, particularly her view that the French philosopher did not stress rights so much than a mental predisposition toward an early form of a "liberalism of fear" (p. 89). For Shklar, Montesquieu's early liberalism of fear is the attempt to avoid above all cruelty, unnecessary suffering and brutal punishment. The French thinker favored a rather minimalist conceptualization free of utopian dimensions; its aim and major purpose was to achieve a decent society marked by the absence of fear.

Shklar also discussed the way Montesquieu was received in the newly emerging American republic. She argued that if he had lived long enough the French Enlightenment philosopher

would have been pleasantly surprised at the echo that *The Spirit of the Laws* received among the American Founding Fathers, particularly in the context of the debates surrounding the United States Constitution. Shklar describes Montesquieu as a mediator not only between Europe and America but also as a "bridge between a traditional and a modern idea of constitutional government" (p. 111). For Americans it did not matter from where Montesquieu came and in which context he wrote. In a very different environment and social and political context, his new theory about the separation of powers could still seem to make perfect sense, even though it was a misreading of the actual English constitution.

Shklar's study of Montesquieu was welcomed, especially by scholars who had long complained that the American-French dimension had often been neglected when studying the republican tradition. Shklar had rightly pointed out "that Pocock's reconstruction of the 'Atlantic republican tradition' had given us *Hamlet* without the Prince by somehow forgetting France" (Wright, 2007: p. 152). This was obviously something that Shklar's Montesquieu interpretation tried to correct.

Shklar also devoted a number of essays to political theory's methodological problems. 'Learning without Knowing,' for example, was the attempt to tackle two problems, that of 'surplus meaning' and that of the type of knowledge that the humanities and social sciences produce (Shklar, 1998a). When old ideas are interpreted in changing contexts, particularly in times of reform and democratization, this poses a challenge to which history and the history of ideas have to respond. According to Shklar, the sociologization of the history of ideas ran into the risk of paying too much attention to quantitative detail. She warned that specialization could narrow the mind (Shklar, 1998a). At the same time one should not go to the other extreme by conflating values and intentions of the more radical kind with good history writing. Detachment from politics was part of the ethics of responsibility as Weber, whom Shklar referred to, knew only too well (p. 126). Shklar conceded that Weber's ideal was hard to achieve. Particularly on-science practitioners will never gain the same level of security of knowing and knowledge (p. 126). The demand for producing useful knowledge in the humanities and social sciences was therefore loaded with risks and ambiguities. In such a situation Shklar recommended organized skepticism and self-control against prophets and gurus (p. 128).

In another essay Shklar voiced her concern about the interpretative turn in the social sciences (Shklar, 1998b). If intellectual influences, intentions of the writer, and specific historical constellations had no bearing on the actual texts in question, as, for example, Ricoeur has argued, the texts itself would be subject to a rather impoverished reading. Not taking intentions, desires, and wishes of actors involved into account would render not only social action meaningless for the participants, but for the more professional observers of social action (such as social anthropologists, historians, and sociologists) the object of their study would simply disappear. To see the reading of the text as something that is identical with human action blurs all boundaries of the different forms or appearances of existence, i.e., any social action could simply be regarded as 'reading.' Shklar suspected that the real motive behind such argumentation is not only to establish hermeneutics as a leading epistemological instrument in the modern social science and arts, but also to defend the intellectual hegemony and almost absolute position of the interpreter. The thus 'secularized,' revamped idea of the hermeneutic circle serves no-one but the new absolute position of the interpreters themselves.

Transatlantic Encounters of a Different Kind (1987–90)

While Shklar's trilogy on Rousseau, Hegel, and Montesquieu can be read as an attempt to make sense of modern European conceptualizations of liberty and its 'psychological' preconditions, a preoccupation with American political theory and the American intellectual tradition meant obviously not just touching on questions of liberty under different social and political circumstances but also taking transatlantic communication and exchanges into account. Shklar's 'optimal marginality' was one of the reasons why she remained skeptical of answers that seemed to her to be either too one-dimensional or too complacent, particularly when they appeared as grand narratives, be it in the form of American exceptionalism or in the form of a rather arrogant 'whig' history of American liberalism.

Many of Shklar's American writings were directly or indirectly an engagement with Hannah Arendt. Shklar admired Arendt but Shklar also felt that something was missing in her work. She often agreed with what Arendt had to say, the unprecedented social and political conditions under which the American Republic was first conceived, the success the Founding Fathers had in absorbing the revolutionary spirit and energy of the people and in preserving the country's political institutions, and the relative success and achievements of the American Revolution when compared to the problems that resulted from the French Revolution. But Shklar also identifies what was completely absent in Arendt's account: that the American Republic had to fight a Civil War in order to secure the earlier promises of the Constitution, particularly in relation to the question of citizenship. Arendt also appeared weak when it came to contemporary issues. According to Shklar, she had little knowledge of post-Civil War history, Southern politics, race relations, and the more contemporary constitutional issues, which dealt with citizenship.

Shklar also differed from Arendt in her particular interpretation of the novel environment that the Americans found themselves in. Using an expression first coined by Emerson, Shklar distinguished between the so-called 'party of hope' and 'the party of memory.' The former position was represented by Tom Paine and Thomas Jefferson and referred to the rejection of and radical rupture with almost everything that related to European history (p. 96ff); Paine and Jefferson not only insisted firmly on living in the present, but their attitude also allowed them to nurture bright hopes for the future. The latter position was represented by John Adams and to a certain extent by James Madison. Adams and Madison suggested taking a closer look at the past in order to find out exactly what had gone wrong with classic European republicanism. This view was much more pessimistic in its outlook than Jefferson's and Paine's; in essence, it was what led this faction of the Founding Fathers to construct certain built-in security mechanisms within

the Constitution. As Shklar pointed out, both views, along with the public discussion of them, shaped what Lipset has called the First New Nation. There was thus not one monolithic way to come to terms with a new beginning. Shklar's interpretation threw a more sophisticated light on the beginnings of the republic than Arendt's did.

In 1990, at the annual meeting of the American Political Science Association in San Francisco, Shklar delivered a groundbreaking presidential speech entitled 'Redeeming American Political Theory' in which she tried to situate the emergence and history of American political ideas in the context of real power struggles (Shklar [1991]/1998). She insisted that political ideas and reflections were not limited to academic or scientific discourse but could also be encountered outside of academia, most prominently perhaps in the form of literature and in popular perceptions and interpretations. In the context of her discussion of the specific *Americaness* of political ideas she referred especially to Emerson, Hawthorne, or Adams to make a case against a rather narrow and limited discourse of both political science and political theory. The main thrust of her speech, however, was directed against the taken-for-granted assumptions of American exceptionalism and liberalism, and that of the relevance of political theory for political science. According to Shklar, liberal exceptionalism was unable to deal adequately with the darker side of American history. The alternative that Shklar presented was not only much more plausible it also showed that political theory had practical and moral implications and at times, as in the case of Emerson, broad educational impact.

Shklar had always been unhappy with a political theory that did not pay attention to specific historical contexts and constellations out of which political ideas emerged. At the same time she was aware that to abstract and universalize from specific historical situations would be equally problematic. A masterful example of a much more balanced discussion is her essay 'Positive Liberty, Negative Liberty in the United States' (Shklar, 1998c). Against Berlin's notion of negative liberty, Shklar stresses that at least in America rights emerged as means that would allow people "to realize goals *against* others" (p. 111f, emphasis in the original). In America, insists Shklar, the fight between master and slave was not just a Hegelian fantasy but real. For her, the fight against slavery was a fight for "freedom itself," it was "a way of political life" (p. 112). The claiming of rights was an inseparable part of that struggle. As Shklar showed, the idea of rights was much more important to the history of American liberalism than the Europeans' liberal distinction between positive and negative liberty (Shklar, 1998c).

In *Faces of Injustice* (1990), which followed on from her deliberation of the limits of negative liberty, Shklar suggested a change of perspective: injustice might be better understood as something that is not just the negative counterpart to justice. Injustice must be studied as a phenomenon in its own right, something that needed to be conceptualized in its own peculiar dimension. This needed to be done independently of 'grand theory' constructions in search of a *summum bonum*. With her critique Shklar aimed at a defense of a barebones liberalism which remained compassionate while at the same time remaining antisystemic in its conceptualization.

Shklar argued that in contrast to advocating distributive models there existed always a skeptical political theory tradition, which provided guidance and contained critical reflections in relation to injustice. For her, the skeptical tradition had the advantage that it regards injustice not just as an absence of justice or just procedures but as occurring "continuously within the framework of an established polity with an operative system of law, in normal times" (p. 19). The skeptics knew this – hence their interest in discussing concrete cases and situations. In a way skeptical philosophers like Plato, Augustine, and Montaigne were first and foremost exemplary story tellers, not system builders.

Shklar concluded that to give injustice its due demands a different perspective and different type of narrative. A good start would be to identify, recognize, and listen to victims of injustice. In effect, such a new critical approach could tell us more about the many faces of injustice rather than following the false hope of striving for an ever more perfect state of justice, including the idea of a perpetual amelioration of the laws.

In *American Citizenship: The Quest for Inclusion* (1991), Shklar elaborated on some of the arguments from *The Faces of Injustice* by exploring the concepts of political and social rights. She was aware that political membership remained of primary importance as it constituted the referential framework for all other aspects. She showed that to insist only on formal membership and citizenship was to neglect the rich connotations of citizenship. Shklar's argument suggested that political belonging (as expressed in voting) depends on earning. After all, one had to be a part of a political community first before the standing and status that derives from being able to provide for oneself can be acknowledged. However, this did not necessarily imply that the social world and earning one's living have merely derivative functions. In contrast, Shklar suggested that there always existed a strong relationship between the two. With reference to American history, Shklar showed that citizenship would be an empty shell if deprived of these concrete social connotations.

Reflections on Obligation and Exile (1991–92)

Toward the end of her life, Shklar had come to realize that the theme of exile and emigration had the potential of throwing an entire new light on the history of obligation and loyalty. To be sure, Shklar had always felt that the story of exile sat uncomfortably with the ideal of belonging. In a discussion of Michael Walzer's *Interpretation and Social Criticism* she had criticized Walzer's model interpreter whose criticism supposedly worked differently because in contrast to the 'discoverer' or 'inventor' type who either founded a religion or a paradigm (the prophet or discoverer), or functioned like a neutral and somewhat distant 'constitutional legislator' (the inventor), the interpreter belonged to a community, could work from within, and was therefore 'less manipulative' (Shklar, 1998: p. 378). For Shklar, Walzer's argument was too much group- or community-centred; it gave too much credit and had too much confidence in the shared understanding and values that underlie community life. While Shklar did not exclude the possibility that such communities could exist, for her such

a presupposition did not sit easily with the experiences of conflict, or the pluralism of interests in modern representative democracies, nor did it give enough weight to individuals and their right to hold opinions *as individuals*.

For Shklar the perspective of exile threw a different light on obligations. Exile, so she noted, was a fundamental human experience that had been dealt with extensively in history and literature. However, surprisingly little had been said about it in terms of political theory – something that Shklar attempted to remedy (Shklar, 1998: p. 57). The exile perspective allowed her to explore and discuss various aspects and themes of political thought – conditions for submission to rules, political obligation, etc. – from a different angle. It also implied a form of extreme decision making, often engaging "the entire personality" (p. 59).

According to Shklar, the fate of modern exiles showed some distinct features. As Shklar points out, Athens and Rome, at least in their early democratic and republican periods, emphasized the public character and just procedures of their polities and demanded both obligation and loyalty to them. In contrast, many modern states have failed by turning state apparatuses into organizations where "governmental illegality" violated and disrupted civil society and the political process to the effect that "political loyalty may survive but not obligation to obey the law" (p. 48). Shklar stressed that exiles, both those who left but also those who went into 'internal exile' and tried to maintain their clear private conscience, had absolutely no obligations to such a state, country, or government. The difference between classical and modern exiles was predominantly marked not by the effort to avoid civil war but was based on the individual's critical judgment and the conscientious rejection to follow what is demanded of him or her. To put it differently, massive exit virtually tested the legitimacy of the modern state (p. 59).

Shklar was painfully aware that today's emigrants and exiled face even more challenging conditions. In many instances there is no host country to offer asylum. There often are no foreign exile and no country to escape to. Most of today's refugees find themselves 'in pure limbo' a situation which evokes moral concern, even moral outrage. Those who are outraged and show solidarity find themselves in a solitary Thoreau-like situation, that is, neither can they join a liberating force nor is it always possible to identify fully with the many refugees due to the lack of detailed knowledge, physical distance, culture, and language etc. As Shklar rightly observes, there is no 'we' here, and, in any case, what exactly could loyalty and obligation refer to, or what kind of notions could they entail in such a situation?

For Shklar exclusionary practice is often the mother of loyalties of often dubious quality and must sometimes be worrying. One conclusion that can be drawn from the modern experience is that cultural and national cohesion remain overrated ideas, eventually causing and even prolonging the conditions in which old and new injustices thrive. Shklar is aware that citizenship might not be the solution to all problems but it still remains a first important step toward preventing injustice, for "injustice not only cancels obligations and undermines loyalties, however resilient the alternatives many seem, it also engenders the conflicts between obligation and the affective ties that bind us" (p. 55).

Shklar's Legacy

Judith Shklar died of a heart attack in 1992. In a commemorative service Stanley Hoffmann, Shklar's best friend at Harvard, pointed out that they both were "survivors from the European catastrophe" (Hoffmann, 1992, in Memorial Brochure: p. 13). Both had become "liberals without illusions" (Hoffmann, 1992) who abhorred the deadly consequences of ideologies but who also valued political theory traditions that served as a bulwark against cruelty and potential atrocity. Above all, Shklar was distinguished by her curiosity and honesty, something that also shone through in her teaching and writing. Hoffmann stressed how important it was to see the connection between Shklar's "experience as a refugee as well as her later life as an immigrant in America and her outlook on power" (Hoffmann, 1993: p. 174). There exist two political science approaches: "those who study power because they like to exert it and those who study it because they fear it – those who would like to ride the horse of power and those who are scared of being trampled by it" (Hoffmann, 1993). Shklar clearly belonged to the latter category. For Hoffmann, Shklar's most important contribution lay in studying the qualities, the moral costume, and the political-psychological dimension of citizens. Montesquieu's observation that "character and government constantly mold each other" was at the heart of her preoccupation (p. 178).

In the same commemoration John Rawls pointed out that there were three central aspects to Shklar's work: a barebones liberalism, whose intellectual foundations go back to Montaigne and Montesquieu; an interest in moral psychology, which was less interested in individual perception than in its political dimension; and a certain form of skepticism *vis-à-vis* grand theories (Rawls in Memorial Brochure, 1992: p. 7). Dennis Thompson, a former student turned colleague, concurred with Rawls but added that while Shklar's skepticism was directed against grand theory, this was born out of common sense about grand theory's own limited historical horizon and function.

Another commentator, James Miller, saw Shklar mainly as a moral psychologist. As such she shared many concerns with fellow political theorists, particularly Isaiah Berlin, Hannah Arendt, and Michael Walzer; however, she also disagreed with them profoundly. While Shklar respected Berlin but disliked his rather snobbish attitude and his attempt to blend into the UK elite, Hannah Arendt, in turn, got lost in republican abstractions in her book *On Revolution* (a book that, as Miller rightly points out, she hated) and Michael Walzer was too communitarian for her taste. While Shklar shared some characteristics and habitus forms with fellow refugees and immigrants, she never became a joiner. She would pursue her own Montaigne-informed, pyrrhonic-style course in which her own attempts did not build up to any grand theory but instead convincingly managed to show that "we are strangers to one another and [that] we are too ignorant to judge each other" (Miller, 2000: p. 818).

Such a 'pyrrhonic' form of thinking might be explained through Shklar's own experience of exile, which developed into a habit of thought. Jonathan Allen observed that "exile left another, deeper imprint on Shklar's work." It led her "to adopt an outlook on politics characteristic of those minorities peculiarly vulnerable to exile, victimization, and the exercise of

arbitrary power." It finally turned Shklar's liberalism of fear into "a liberalism for grown-ups" (all quotes in Allen, 1998: pp. 446–550).

Short- and Long-term Memory during Infancy and Early Childhood across Cultures

Patricia J Bauer, Emory University, Atlanta, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Memory is a multidimensional construct that is evident from early in life yet undergoes a protracted course of development. This article features elaboration of the construct of memory with emphasis on distinctions between short- and long-term memory. It also features discussion of data on developmental changes in memory. Neurodevelopmental and social and cultural influences of change in memory are highlighted.

The singular noun – *memory* – implies a single entity. In fact, memory is not a unitary construct. There are many different kinds and types of memory, each with its own distinctive characteristics. The focus of this article is short- and long-term memory. As the names imply, short-term memory lasts only seconds or minutes before fading away, whereas long-term memories may last a lifetime. A major goal of this article is to describe the course of development of these different types of memory over the first years of life. A second goal is to describe some of the mechanisms of development, including changes in neural systems and social and cultural factors.

Short-Term and Working Memory

Short-term memory operates over brief spaces of time: on the order of 10–30 s. Working memory also is temporally limited but differs from short-term memory in another way: it involves manipulation of information during temporary storage.

Verbal Tests and Developments in Childhood

Tasks of short-term memory require encoding and temporary maintenance of information. Tests of working memory impose the additional constraint that during the brief delay, the subject must operate on the information in some way. An oft-used test of short-term memory involves listening to a string of digits (e.g., 8-2-4-5-7-1) and then repeating them after a brief delay (8-2-4-5-7-1). To make this simple task a measure of working memory, the requirement to reverse the order of the sequence is imposed. In this case, the correct response is 1-7-5-4-2-8.

Short-term and working also have capacity limitations that change with development. Whereas the memory span for adults is seven items (±2), the short-term memory spans for children 9, 7, 5, and 2 years of age are estimated to be six, five, four, and two items, respectively (Dempster, 1981). Critically, in both adults and children, memory span varies as a function of domain-specific knowledge. In domains in which children have greater expertise than adults, the typical age-related advantage for adults relative to children is reversed (e.g., Chi, 1978).

A variety of paradigms have been used to examine the simultaneous maintenance and manipulation of information in working memory, including the *reading span task* in which subjects read a series of sentences and attempt to remember the sentence-final word of each (e.g., Daneman and Carpenter, 1980). Performance on these tasks shows the same pattern of age-related improvements with age as are apparent on tests of short-term memory. Typically, the absolute number of items that can be retained in working-memory tasks is reduced relative to short-term memory tasks, however.

Nonverbal Tests and Developments in Infancy

A common means of testing the duration of short-term or working memory in nonverbal or preverbal organisms is with the *delayed-response task*. The task involves hiding an object in one of multiple locations, imposing a delay, and then allowing the subject to retrieve the object. Based on this task, the temporal extent of working memory in infancy increases from 0 s at 8 months to 8 s at 12 months (e.g., Diamond and Doar, 1989).

Estimates of short-term or working-memory capacity can be obtained from the *change-detection paradigm*. Infants observe two monitors side-by-side, each with colored squares that blink on and off. On one monitor the stimuli remain constant across trials whereas the color of the stimulus on the other monitor changes on each trial. If infants notice the color change, they look longer at the novel stimulus. The capacity of memory is evaluated based on the number of squares in the display. Capacity increases from 1 to 2–3 elements over the first year of life (Oakes et al., 2007).

Long-Term Memory

Long-term memories may last an indefinite period of time and the capacity of long-term memory seemingly is infinite. A major distinction in long-term memory is between that which is deliberate and strategic and that which is incidental. Incidental long-term memories are of unique episodes and experiences (episodic memory) and may be of high personal relevance and significance (autobiographical memory).

Deliberate and Strategic Memory

Especially in academic settings, individuals may consciously work to maintain memories and use strategies to do so. Although there is evidence of deliberate memory even in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23064-X

infancy (see Roebers, 2014), the most striking age-related changes occur in the later preschool and elementary school years. During this period, children become more strategic in their memory behavior, employing a greater number and variety of strategies and deriving greater benefit from them (see Bjorklund et al., 2009; for a review).

In a seminal study, Flavell et al. (1966) found that verbal rehearsal – repetition of the names of to-be-remembered picture stimuli – was more common in older than younger children. Whereas only 10% of the 5-year-olds engaged in rehearsal, 85% of the 10-year-olds did. The older children also remembered more. Subsequent studies observed that even when younger children rehearse, they do so less effectively. Younger children are more likely to repeat only a subset of the stimuli they are required to remember (*passive* rehearsal) whereas older children repeat more items (*active* or *cumulative* rehearsal; e.g., Guttentag et al., 1987). When young children are trained to use the more effective cumulative rehearsal, recall improves, though not to the levels observed in older children (e.g., Cox et al., 1989).

Use of sorting or clustering of related items at the time of study and/or test shows similar developmental trends. Relative to older children, younger children are less likely to spontaneously group similar items together into categories as they are studying them and at the time of recall, they are less likely to report items in groups or 'clusters' from the same category (e.g., Bjorklund et al., 1992). When younger children are explicitly instructed to sort, they use the strategy and experience a concomitant increase in the number of items recalled, yet still do not recall as many items as older children (e.g., Carr and Schneider, 1991). By later in the school years, the repertoire of strategies that children use has expanded substantially, children use the strategies spontaneously, and they derive mnemonic benefit from them. The more strategies used, the greater the level of recall.

Incidental Episodic Memory

Long-term episodic memory supports retention of information about unique events that can be located in a particular place and time (Tulving, 1972). It has a protracted course of development, beginning in infancy and extending into adolescence.

Episodic Memory in Infancy

Over the first years of life there are developmental changes in long-term memory for specific episodes along a number of dimensions. Because infants are preverbal, a common means of testing long-term memory is with nonverbal imitation-based tasks in which objects are used to demonstrate an action or sequence of actions that infants are invited to imitate. The task is an accepted analog to verbal report (e.g., Bauer, 2007; Carver and Bauer, 2001).

A salient change in episodic memory over the first 2 years of life is the length of time over which it is apparent. At 6 months, infants remember for 24 h whereas by 9 months, they remember over delays as long as 5 weeks (Lukowski and Bauer, 2014; for a review). Thirteen- to fourteen-month-olds remember actions over delays of 4–6 months (Bauer et al., 2000; Meltzoff, 1995), and by 20 months, children remember for as many as 12 months (Bauer et al., 2000). Infants also recall the temporal order of multistep sequences, though retaining order information presents a cognitive challenge to young infants, in particular. Age-related differences in ordered recall are especially apparent under conditions of greater cognitive demand, such as when less support for recall is provided, and after longer delays (Bauer et al., 2000).

Over the first 2 years there also are changes in the robustness of memory for specific episodes. For instance, there are changes in the number of experiences that seem to be required in order for infants to remember. Whereas 6-month-olds require six exposures to events in order to remember them 24 h later, 14-month-olds require only a single exposure to support recall over 4 months (Bauer, 2013; for a review). Another index of memory robustness is the extent to which it is disrupted by interference. One form of interference that has been studied in infancy is changes in context between encoding and retrieval. With development, infants are increasingly able to show evidence of memory even over changes in (1) the size, shape, color, and/or material composition of the objects used in demonstration vs test; (2) the appearance of the room at the time of demonstration vs test; (3) the setting for demonstration of the modeled actions vs test; and (4) the individual who demonstrated the actions and the individual who tested for memory for the actions (see Lukowski and Bauer, 2014; for a review).

Episodic Memory in Early Childhood

Beginning in the third year, verbal means of assessment become a viable means of testing long-term memory. This permits testing of controlled laboratory events as well as events from outside the laboratory. Early studies of young children's memories for the events of their own lives focused on everyday, routine events. The research revealed 'minimalist,' yet nevertheless accurate, reports by children as young as 3 years of age. The children's reports included actions common to the activities and almost invariably, the actions were mentioned in the temporal order in which they typically occurred (Nelson and Gruendel, 1986). The actions also were those most central or important to the event, suggesting that children appreciated the goals of many of the events of their lives.

Young children also form memories of unique events. For example, in Hamond and Fivush (1991), 3- and 4-year-old children recalled a trip to Disney World they had taken either 6 or 18 months previously. The amount they remembered did not differ as a function of the delay. Moreover, the older and younger children did not differ in the overall amount of information they reported about the event. The older children tended to provide more elaborate responses to memory questions, relative to the younger children, however.

There are also suggestions of developmental changes in the length of time over which memories of unique events are retained. For example, Quas and her colleagues assessed children, 3–13 years of age, for their memories for a painful medical procedure that they had experienced between 2 and 6 years (Quas et al., 1999). Children who were older at the time of the procedure provided clearer evidence of recall of it. In contrast to the older children's detailed reports, the reports of the younger children were vague. Moreover, none of the children who had been 2 years of age at the time of the procedure demonstrated clear memory for it later, whereas

most of the children who had been at least 4 years old at the time of the procedure remembered it.

With age, children report different types of information: older children and adults focus on what is unique or distinctive about an experience whereas younger children seem to comment on what is common across experiences. For example, in Fivush and Hamond (1990), in response to the interviewer's invitation to talk about going camping, after providing the distinctive information that the family had slept in a tent, a 2.5 year old went on to report on the more typical features of the camping experience. In total, only 48% of the information that the children reported was distinctive. This pattern changes over time: By 4 years of age, children report about three times more distinctive than typical information (Fivush and Hamond, 1990). Greater focus on the distinctive features of events is associated with increases in the ability to remember episodes that are truly unique from one another.

Incidental Autobiographical Memory

Changes in how long unique episodes are remembered and in the distinctiveness of events remembered are critical ingredients in the development of a particular type of memory for specific events that becomes apparent during the preschool years, namely, *autobiographical* memory. Autobiographical memories are of events and experiences that make up one's life story or personal past. They differ from 'run-of-the-mill' episodic memories in that they are infused with a sense of personal involvement or ownership in the event. They are memories of events that happened to one's self; in which one participated; and about which one had emotions, thoughts, reactions, and reflections. It is this feature that puts the 'auto' in '*auto*biographical.'

Emergence in the Preschool Years

Over the preschool years, children's memories take on more and more autobiographical features (see Bauer, 2007, 2014, for discussions). For example, from a very young age, children include references to themselves in their narratives: "*I* fell down." With age, they increasingly pepper their narratives with the subjective perspective that indicates the significance of the event for the child (Fivush, 2012). For example, they go beyond comment on the objective reality of 'falling down' to convey how they felt about the fall: "I fell down and *was so embarrassed* because everybody was watching!" It is this subjective perspective that indicates the significance of the event to one's self.

There are also changes in the marking of events as having taken place at a specific place and time. For instance, children increasingly include specific references to time, such as 'on my birthday' or 'last summer' (Pathman et al., 2013). Markings such as these not only establish that an event happened at a time different from the present, but they begin to set up a timeline along which an organized historical record of when events occurred can be constructed. Children also include in their narratives more orienting information, including where events took place and who participated in them (e.g., Fivush and Haden, 1997). These changes serve to distinguish events from one another, thereby making them more distinctive.

Finally, over the preschool years, children include in their narratives an increasing number of elements that suggest rich detail that would contribute to the sense of vivid recollection. They include more intensifiers ("Cause she was *very* naughty"), qualifiers ("I *didn't like* her video tape"), elements of suspense ("And *you know what*?"; examples from Fivush and Haden, 1997; see also Ackil et al., 2003). In Fivush and Haden (1997), for example, children went from using approximately four descriptive terms per event at age 3.5 years to using 12 such terms per event at 6 years. The result is a much more elaborate narrative that brings both the storyteller and the listener to the brink of reliving the experience.

Changes in Childhood and Adolescence

Age-related changes in autobiographical reports continue throughout the elementary school years and beyond. One obvious change is in the breadth or completeness of children's narratives. Like a good newspaper story, a 'good' autobiographical narrative includes the *who*, *what*, *where*, *when*, *why*, and *how* of events. Younger children include fewer of these essential elements, relative to children 10–11 years of age (e.g., Bauer and Larkina, 2013; Bauer et al., 2007).

Even once children's narratives become more complete, there is continued development in autobiographical narratives. During the transition from late childhood to adolescence, personal narratives become more elaborated and they come to feature more biographical information that links events to one another (Habermas and Paha, 2001). During this same period individual identity becomes a critical issue, and personal stories begin to take on greater significance (e.g., Habermas and Bluck, 2000). With the cognitive and social advances of adolescence, individuals are able to organize and organize memories of their past experiences into a life narrative, integrating a sense of past, present, and future into a personal timeline (Habermas and Bluck, 2000).

Mechanisms of Change in Short- and Long-Term Memory

A complete understanding of the mechanisms of developmental change in short- and long-term memory ultimately will entail multiple levels of analysis, from the neural systems that support memory to the impact of culture on what is regarded as important to remember and how it is to be expressed.

Neural Systems of Memory

Early in life, a significant determinant of memory is the developmental status of the neural system responsible for it. The formation, storage, and later retrieval of memory traces depend on a multicomponent network of brain structures, including some in the temporal lobe and others in the cerebral cortex. When we experience an event, the sights, sounds, smells, and tactile sensations associated with it register in primary and association regions distributed across the cortex. For this distributed representation to endure as a memory trace, it must be stabilized or *consolidated* for long-term storage (McGaugh, 2000). Later retrieval of a memory trace depends on

prefrontal cortex, in particular (e.g., Eichenbaum and Cohen, 2001; Zola and Squire, 2000).

Some aspects of the temporal-cortical network that supports memory develop early. Others undergo a protracted course of development that extends into adolescence (see Bauer, 2006, 2007, 2014; Richman and Nelson, 2008, for discussions). The long, slow course of development of the neural structures and network responsible for memory means that throughout infancy and for much of childhood, the processes by which new memories are formed, stabilized, and integrated into long-term storage are relatively ineffective and inefficient. As a result, memories are vulnerable to disruption and interference and thus to forgetting (see Bauer, 2009; for discussion). The younger the child, the greater the vulnerability. The vulnerability of memory traces in childhood contributes to more rapid forgetting of events and experiences, ultimately resulting in the phenomenon of childhood amnesia (the relative paucity of memories of events from the early years of life: Bauer and Larkina, 2013; Bauer et al., 2007).

Social and Cultural Influences on the Development of Memory

From some of its earliest manifestations, memory is influenced by the social world (Nelson and Fivush, 2004). Social influences from the family to the larger cultural group shape what children ultimately come to view as important to remember and even how they express their memories.

Familial Factors

Young children learn to craft personal narratives by participating in conversations about past events with more skilled partners, typically their parents. Adults exhibit two different styles when they engage in memory talk with their children (Fivush, 2014; for a review). Parents who frequently engage in conversations about the past, provide rich descriptive information about previous experiences, and invite their children to 'join in' on memory conversations, are said to use an *elaborative* style. In contrast, parents who provide fewer details and instead pose specific questions to their children (e.g., "What was the name of the restaurant where we had breakfast?"), are said to use a *repetitive* or *low elaborative* style.

Stylistic differences have implications for children's memory narratives. Children of parents using the elaborative style report more about past events than children of parents using the repetitive or low elaborative style (see Fivush, 2014; for a review). The elaborative style is thought to provide the young child with, in effect, a 'prototype' of the narrative frame into which information about the actors, actions, intentions, and affective experiences of those involved in an event is inserted. The advent of the narrative organization allows the child to begin to construct the personal history that is the hallmark of autobiographical memory. Consistent with this suggestion is evidence of cross-lag correlation from maternal style variables at 40 and 46 months to child verbal report variables at 58 and 70 months of age: Maternal use of a more elaborative style facilitates children's independent narrative accounts (Reese et al., 1993). Effects of elaborative style on children's memory extend beyond the reminiscing context to imitation-based tasks (Bauer and Burch, 2004). Analogous effects are observed in deliberate memory tasks (Larkina et al., 2008).

Cultural Factors

The larger cultural milieu also influences the development of memory (see Wang, 2014). Most of the research that makes this point has involved comparisons of children from Eastern and Western culture groups. It has been found that the early autobiographical memory reports of children from Asian cultures include fewer references to themselves and fewer personal evaluations, relative to reports from children in the United States. In addition, the autobiographical narratives of children from Asian cultures tend to feature generic as opposed to specific events, and they are shorter and less detailed, relative to those provided by children in the United States (e.g., Wang et al., 2000). As reviewed by Wang (2014), these differences may be associated with variability in cultural perspectives on the value and goal of reminiscing. Indeed, Asian dyads engage in talk about the past less frequently than American dyads, and Asian mothers are less elaborative than American mothers, especially when talking about emotional experience (e.g., Wang et al., 2000).

Conclusions

Short- and long-term memory are apparent even in infancy yet undergo protracted courses of development. In the case of short-term and working memory, developmental changes are apparent in the duration over which information can be held in mind and manipulated and in the capacity of the memory systems.

Long-term memories may be either deliberate and strategic or incidental. Incidental memory may be of everyday or routine events or of specific events located in place and time, so-called episodic memories. Episodic memories of personally relevant or significant events are considered autobiographical. Both the number and efficacy of memory strategies increase over the preschool years and especially in childhood. Children experience concomitant improvements in the amount of information they remember. Episodic and autobiographical memory also become more robust over the preschool years and beyond, resulting in a larger corpus of memories of unique and distinctive events, many of which are personally relevant and even self-defining.

Developments in memory are multiply determined, by factors ranging from the neural structures and network that subserves memory, to the social and cultural influences on what is considered important to remember and express. Neural system developments result in changes in the vulnerability of memories to forgetting, contributing to the development of childhood amnesia. Social and cultural factors contribute to individual and culture group differences in the robustness of autobiographical memories across the lifespan.

Short Term Memories, Theories of

Evie Vergauwe and Nelson Cowan, University of Missouri-Columbia, Columbia, MO, USA

Abstract

This article discusses how information that is no longer available for perception is maintained mentally. To do so, the psychological concepts of short-term memory and working memory are introduced. Next, two different research traditions in the literature are discussed, together with the key theories and findings of each tradition. From that, we will conclude that the general way to maintain information over a short period of time is by focusing attention on it. For verbal material, such as a phone number, people have an extra mechanism available that consists in articulatory rehearsal.

What is short-term memory (STM)? One very popular example of STM is the capacity to remember a telephone number from the phone book over the short term, that is, at least till one is able to dial it. Within psychology, the limited-capacity system underpinning human's ability to maintain mentally information that is no longer available for perception is referred to as STM. Maintaining an address, a vehicle registration plate, a grocery list, or driving directions are just some of the most frequent examples of the need to maintain some information over a brief period of time in our daily life. How is one able to keep information in memory when it is no longer physically available, that is, when one can no longer hear, see, feel, taste, or smell the information to be maintained?

As will be seen, the concept of STM is very closely related to another concept in psychology, that of working memory. Investigators differ in their definitions but the authors adhere to the following popular distinction. While the concept of STM specifically refers to the ability of storing information over a short period of time (a matter of seconds), working memory refers to the ability to maintain mentally information in an active and accessible state, while concurrently and selectively processing some additional information (Baddeley and Hitch, 1974). As such, while both concepts refer to maintaining information over the short term, working memory is specifically concerned with doing so while processing new incoming information. Thus, if one were to maintain a phone number while just sitting there doing nothing else, psychologists would say that the person is using STM. If, however, one were trying to remember the same phone number while watching a music clip on YouTube, psychologists would say the person is using working memory. Of course, this does not necessarily mean that the person is using a whole other set of cognitive mechanisms and processes to fight against forgetting of the phone number. It just means that, depending on the exact conditions in which one is trying to maintain information, the psychological concept one would refer to could be either STM or working memory.

The ever-changing and very dynamic environment we are currently living in means that one is most often trying to maintain information while doing something else. Other examples of using working memory in daily life are paying cash, which requires one to maintain how much one already gave while calculating how much more one should give to pay the total amount; taking notes in class, which requires one to maintain and write down the beginning of a sentence while listening to the ongoing stream of information; or simply being on Facebook, which frequently puts one in a situation in which he or she has to maintain the content of an ongoing chat conversation with one friend while processing the incoming news feeds of other friends.

From Short-Term Memory to Working Memory

While the concepts of STM and working memory both refer to maintaining information over a rather short period of time, other faculties have been proposed for maintaining information over longer periods of time. The distinction between a short-term and a long-term component of memory had been proposed by William James (1890), who distinguished between a temporary primary memory and a more durable secondary memory, and gained popularity among psychologists when Donald Hebb suggested in 1949 the existence of two types of memory, STM and long-term memory (LTM), with the former depending on temporary electrical activity in the brain and the latter on more durable neurochemical changes in the brain, a view that was supported by Brown (1958) and Peterson and Peterson (1959). Miller (1956) suggested that the capacity of STM is limited so that people can retain only about seven items. Some alternative proposals notwithstanding (e.g., Melton, 1962), by the late 1960s, the distinction between STM and LTM was widely accepted in the memory field. Moreover, the distinction had been incorporated in one of the most influential models of human memory, the model of Atkinson and Shiffrin (1968, 1971).

The Atkinson–Shiffrin (1968) model (also known as the multimemory model, the multistore model, or humorously as the modal model because it was typical of a number of models of the era) proposed three separate memory stores, differing in their function, capacity, and duration. Information was assumed to flow from the environment through a series of brief sensory registers, which are part of the perceptual system, into a single short-term store. This limited-capacity short-term store was thought of as a unitary system responsible for encoding information into and retrieving information from a long-term store, this third type of store having a much larger capacity and capable of more or less permanent storage. Importantly, the unitary short-term store was conceived as an active memory, an operating

memory capable of both storing and manipulating information. That is, Atkinson and Shiffrin assigned the role of working memory to the short-term store by assuming that it could handle both processing and storage of information instead of only storing information.

There was, however, little empirical evidence backing up this idea. Also, Shallice and Warrington (1970; Warrington and Shallice, 1969) reported the case of a patient showing severe impairment on STM tasks, an impairment that could be accounted for by assuming a defective short-term store. However, if the unitary short-term store is indeed a working memory system that handles both processing and storage of information, then the patient should not only show impaired STM performance, but also a general cognitive processing dysfunction. No such general impairment was found; the patient showed preserved learning and comprehension abilities. This suggested that processing and storage are handled by different systems.

In their seminal 1974 paper, Baddeley and Hitch decided to examine this issue in detail. Instead of studying patients, they studied performance in normal subjects using a dual-task paradigm. In such a paradigm, subjects are required to perform two tasks at the same time. Baddeley and Hitch asked participants to maintain series of digits while performing processing tasks such as reasoning or language comprehension. They reasoned that maintaining series of digits would use a substantial amount of the storage capacity of a limited capacity working memory system. If this working memory system is also used for general processing, then reasoning and language comprehension performance should suffer from the concurrent memory load. This should be so because, when they are performed under concurrent memory load, less capacity would be available for the processing tasks. Contrary to this prediction, it was observed that reasoning and language comprehension was not disrupted by having to maintain three digits concurrently and were only moderately disrupted by having to maintain six digits concurrently. This pattern of results suggested that even if there is some overlap between the system supporting general cognitive processing and the system supporting storage, there seems to be some capacity available for processing that was not taken up by a concurrent memory load of six digits (even though that is near the amount a typical adult can remember and repeat, as shown by Miller, 1956). From this, Baddeley and Hitch concluded that, while there might be a central workspace devoted to processing and storage, storage of information is mainly handled by subsystems that are independent from this central workspace. It was proposed to replace the unitary short-term store by the concept of working memory, which was supposed to be a multiple-component system.

The core of the multiple-component model of working memory of Baddeley and Hitch was assumed to consist of a limited work space, which can be divided between processing and storage activities. In contrast to the unitary view of Atkinson and Shiffrin, however, Baddeley and Hitch did not consider working memory as one entirely flexible system of which all resources can be devoted to either storage or processing activities. Instead, they suggested that the central flexible system interacted with a more peripheral system that can be used for storage, but that is not available for general processing. Once the capacity of the peripheral system is exceeded, some of the capacity or time of the flexible central general-purpose system needs to be devoted to storage. The peripheral component was thought of as a capacity-limited phonemic buffer (also referred to as phonemic rehearsal system and phonemic loop) able to store speechlike information in serial order without drawing on the central component. As such, the observations of Shallice and Warrington (1970; Warrington and Shallice, 1969) could be accounted for by assuming that only the phonemic buffer of the patient was impaired, while the central component of his working memory system was intact. Besides the phonemic buffer for verbal information (e.g., letters, digits, words, and sentences), which is known now as the phonological loop, the existence of a second, comparable but separate, peripheral system was postulated for the storage of visuospatial information (e.g., shapes, colors, locations, and orientations), a system which is known now as the visuospatial sketchpad. In sum, the first widely used model of working memory comprised a central flexible domain-general work space, which can be divided between processing and storage activities (i.e., central executive component) and two domain-specific storage-only components, one for verbal information (i.e., phonological loop) and one for visuospatial information (i.e., visuospatial sketchpad). The first component can be referred to as the central level, the latter components as the peripheral level of working memory.

A Central Level and a Peripheral Level in Working Memory

The Baddeley and Hitch (1974) chapter was an extraordinary inspiration to an ever growing number of researchers in cognitive psychology and cognitive neuroscience. Accordingly, as Saito and Towse (2007) noted, a survey of academics identified the chapter as one of the 100 most influential papers in cognitive science in the last millennium (Millennium Project). At least part of the breadth and extent of its impact and of its longevity has been attributed to the fact that the concept of working memory can be used in two distinguishable ways (e.g., Saito and Towse, 2007; Towse et al., 2007). Indeed, throughout the working memory literature, two different conceptions of working memory emerge. Working memory has been used as a general unitary concept (which Baddeley, 1986; refers to as WMG for working memory general) playing an important role in human information processing by serving both processing and storage operations in ongoing cognition. This WMG conception of working memory can be differentiated from using the working memory concept as a specific model (which Baddeley, 1986; refers to as WMS for working memory specific) with its specific architecture, structure, and processes involved in tasks requiring WMG. Broadly speaking, researchers using the WMG conception have been inspired by the *idea* of working memory introduced by Baddeley and Hitch, whereas researchers using the WMS conception have been inspired by the model of working memory introduced by Baddeley and Hitch in 1974. These

different approaches have resulted in two different research traditions of working memory, each with their respective theories, research methodologies, assumptions, and implications. Indeed, while the WMS tradition has mainly focused on the peripheral level of working memory, the focus of the WMG tradition has primarily been on the central level of working memory, which is closely related to attention. Interestingly, as seen in the following, the traditions have different answers to our question of how information is maintained over a short period of time. Both traditions have, of course, their merits. After presenting key theories and findings of each tradition, it is shown that their answers to our question are actually quite compatible.

Focusing on the Peripheral Level in WMS: Domain-Specific Maintenance Mechanisms

Within the WMS tradition, researchers have mainly aimed at characterizing the peripheral systems of working memory while the central level remained less studied. Concerning the phonological loop, four basic findings and phenomena associated with verbal serial recall led to propose a fractionation of the verbal storage system into two subcomponents. First, the presence of irrelevant and unattended speech disrupts verbal serial recall, an effect referred to as the irrelevant speech effect (e.g., Colle and Welsh, 1976; Salamé and Baddeley, 1982). Second, recall of a series of words or letters is worse when these words or letters sound alike, that is, are phonologically similar, an effect referred to as the phonological or phonemic similarity effect (e.g., Baddeley, 1966; Conrad and Hull, 1964). Third, recall of a series of words is worse for series of long words than for series of short words and this word length effect appears to be caused by the length of time required to pronounce the words rather than by the number of syllables or letters they contain (e.g., Baddeley et al., 1975b). Finally, the requirement to utter continuously an irrelevant sound such as 'the, the, the' (i.e., articulatory suppression) disrupts verbal serial recall (e.g., Baddeley et al., 1984).

Accounting for the ensemble of these phenomena was possible by assuming that the phonological loop consists of two separate subcomponents: (1) a passive phonological store that can hold verbal information in its phonological code for about 2 s and (2) an articulatory rehearsal process that counteracts time-related forgetting of information held in the phonological store by rehearsing its content subvocally. Furthermore, it was assumed that whereas nonauditory verbal information needs to be recoded in a phonological format by the articulatory rehearsal process before it can enter the phonological store, auditory verbal information has direct access to the phonological store. Hence, unattended irrelevant speech goes directly into the phonological store where it interferes with the verbal material stored in there for further recall. As a result, recall performance is impaired. Furthermore, when verbal items stored in the phonological store are phonologically similar, they will have a large number of overlapping phonological features and, as a result, get confused. Hence, their recall will be less accurate. The effect of concurrent articulatory suppression and word length, on the other hand, are accounted for by the articulatory rehearsal loop. Indeed, the utterance of an irrelevant sound is assumed to block the process of articulatory rehearsal, meaning that verbal material stored in the phonological store cannot be maintained through that facility. Finally, the word length effect is thought of as resulting from the fact that longer words take longer to be rehearsed by the articulatory loop and, as such, delay the maintenance of other words through subvocal rehearsal, which results then in forgetting of these words.

Inspired by the substantial work and, scientifically speaking, fast progress in understanding the structure and functioning of the phonological loop, researchers started to explore more in detail its visuospatial counterpart using comparable techniques. A first step in understanding the visuospatial sketchpad was to establish experimentally its existence. Unlike the phonological loop, the existence of a separate system for visuospatial material was postulated by Baddeley and Hitch (1974) more out of theoretical necessity than based on extensive empirical evidence, although there was some; notably a study by Brooks (1968) showing that verbal recall is most readily disrupted by concurrent vocal activity while visuospatial recall is most readily disrupted by concurrent spatially monitored activity (see also Baddeley et al., 1975a). The rationale behind the experimental work that aimed at demonstrating that a visuospatial sketchpad was indeed needed to account for working memory functioning (e.g., Farmer et al., 1986; Logie, 1986; Logie et al., 1990) was the following. Researchers reasoned that, if two separate peripheral domain-specific working memory systems exist, then it should be possible to interfere with each of these systems selectively. To test this, studies (1) used verbal interference techniques such as articulatory suppression and irrelevant speech to demonstrate that these techniques have a disruptive effect on concurrent verbal activities, but not on concurrent visuospatial activities and (2) developed visuospatial interference techniques to demonstrate that these visuospatial analogs have a disruptive effect on concurrent visuospatial activities, but not (or less) on concurrent verbal activities. For example, Logie (1986) used an STM task as primary task to selectively interfere with. Participants were presented with a list of concrete words that had to be recalled after a 10-s retention interval. The domain of the memory task was manipulated by asking participants to maintain the series of words either verbally (i.e., rehearsing the words subvocally) or visually (i.e., creating a visual image of each word and integrating these images into one interactive image). During the presentation and recall of the series of words, participants were either presented with no additional information, with line drawings of common objects and animals on screen for which participants were instructed to ignore them without closing their eyes or looking away, or with spoken names of common objects and animals presented through headphones for which participants were instructed to ignore them. Hearing irrelevant speech was thought to provoke the known irrelevant speech effect on the verbally maintained words, whereas viewing irrelevant pictures was assumed to provoke a similar effect on the visually maintained words. The predicted pattern of selective interference was observed. Irrelevant speech impaired recall performance of verbally maintained words, but not that of

visually maintained words. Irrelevant viewing, on the other hand, impaired recall performance of visually maintained words while it had very little effect on recall performance of verbally maintained words. It was concluded that a visuospatial sketchpad in working memory was needed and the next step was to explore its structure and functioning.

Some studies had demonstrated that concurrent movements disrupt maintenance of spatial information (Baddeley and Lieberman, 1980; Smyth and Pendleton, 1989) and that viewing irrelevant pictures disrupts maintenance of visual information (Logie, 1986; Quinn and McConnell, 1996). These findings seemed to corroborate Logie's proposal of a visuospatial sketchpad that, like the phonological loop, can be fractionated into two subcomponents. Indeed, Logie (1995) suggested that the visuospatial memory system consists of a passive visual store (the visual cache) and an active spatial rehearsal process (the inner scribe), with the latter being related to the control of movement. Logie and Marchetti (1991) explored this idea in a recognition task in which subjects had to maintain either color shades (visual memory) or location sequences (spatial memory). The retention interval between presentation and recognition was filled with either the presentation of irrelevant pictures (visual interference) or a concurrent movement task (spatial interference). The viewing of irrelevant pictures was thought to selectively interfere with the visual passive component, whereas the concurrent movement was thought to selectively interfere with the spatial active component. This selective interference pattern was indeed observed in that spatial memory performance was disrupted by the concurrent movement task, but not by the concurrent irrelevant pictures, while visual memory performance was impaired by concurrent irrelevant pictures but unaffected by concurrent movements.

The findings of Logie and Marchetti (1991) appeared to confirm the fractionation of the visuospatial sketchpad into a passive visual store and an active spatial movement-related rehearsal process. Irrelevant visual input was thought to have direct access to the visual cache where it interferes with the visual material that is stored in there during retention (e.g., color shades). As a result, visual memory performance is impaired when irrelevant visual pictures are presented during retention. The disruptive effect of concurrent movements on spatial memory performance is accounted for by the operation of the active spatial rehearsal process, which is assumed to be related to control of movement. As such, the requirement to perform movements during retention of spatial material blocks the spatial rehearsal process, meaning that spatial material can no longer be maintained by this mechanism with poorer memory performance as a consequence. In the same way, the disruption of spatial recall performance by a perceptuomotor task (e.g., spatial tracking; e.g., Baddeley and Lieberman, 1980) can be explained by assuming that the active spatial rehearsal process was being blocked by concurrent spatial tracking.

Thus, within the WMS tradition, research has resulted in a domain-based fractionation of the peripheral system into a verbal and a visuospatial subsystem, each comprising a rehearsal mechanism independent from the central level of working memory. As such, within the WMS tradition, the answer to our question would be that information is maintained over short periods of time in domain-specific buffers by rehearsing them using a domain-specific mechanism. Importantly, these domain-specific maintenance mechanisms at the peripheral level of working memory are typically assumed to act independently from the central level (e.g., Baddeley and Logie, 1999; Cocchini et al., 2002; Duff and Logie, 2001). Thus, when one tries to maintain a phone number, one would use articulatory rehearsal, which consists in subvocally repeating the digits without the need of focused attention. It should be noted that, although most researchers would agree on the existence of some domain-specific mechanisms, independent from attention and devoted to maintenance, the precise conception of these mechanisms is still a matter of debate (see Jalbert et al., 2011a,b; Jones et al., 2007; Lewandowsky and Oberauer, 2008 for alternative views on the phonological loop; see Klauer and Zhao, 2004; Repovs and Baddeley, 2006; Vergauwe et al., 2009; Wood, 2007 for alternative views on the visuospatial sketchpad).

Focusing on the Central Level in WMG: Domain-General Maintenance Mechanisms

While the WMS tradition has focused on the peripheral level of working memory, the WMG tradition has mainly focused on the central component of working memory as proposed by Baddeley and Hitch (1974). Remember that, in the original multiple-component model, the central work space was proposed to be devoted to processing and storage. In other words, even though domain-specific maintenance mechanisms would exist at the peripheral level, Baddeley and Hitch left open the possibility of there also being a domain-general mechanism of storage at the central level. Interestingly, while this central domain-general storage faculty was left largely unexplored within the WMS tradition (but see more recent research, e.g., Baddeley et al., 2010, 2011), the possibility of domain-general storage was central in the embedded-processes model proposed by Cowan (1988, 1995, 1999).

Cowan described the information processing system as embedded processes: (1) the LTM system, (2) within which, a subset is currently activated, that is, in a temporarily heightened state of activation, and (3) within which, a subset is currently in the focus of attention. While activated memory was supposed to include diverse features of information and to be limited by decay over time and by interference with other information that is alike. The focus of attention, however, was proposed to include coherent, integrated pieces of information (i.e., chunks, see Miller, 1956; for constant recall limited to several chunks see Chen and Cowan, 2009; Cowan et al., 2012) and was assumed to be limited in capacity to about 3–4 chunks (Cowan, 2001). In such model, the limited storage capacity observed in humans is assumed to reflect the limited capacity of the focus of attention that serves as a domain-general storage mechanism. In line with that, several studies have shown that there is a constant storage limit of about 3–4 items in working memory. For example, Luck and Vogel (1997) used a visual-array comparison task in which an array of objects such as colored squares is briefly displayed on computer screen. Next, after a brief delay, a second array is shown and participants had to decide whether the arrays were

the same or different. Typically, performance dropped severely for arrays with more than three to four colored squares and this limit was found to be constant across the number of features in the stimuli. As noted by Cowan (2011), this limit was also found to be constant within an individual, across variations in the complexity of the stimuli (Awh et al., 2007) and the number of items in the array (Zhang and Luck, 2008). Importantly, this limit at about three to four items has not only been observed for briefly presented visual arrays, but also for lists of spoken material. Cowan (2001) suggested that the limit of three to four items occurs under certain circumstances in which items are integrated objects and the circumstances discourage rehearsal or chunking of the items to reduce the load. In line with that, there are several studies that show that memory for spoken lists is limited at about four items in adults when they maintain the information under concurrent articulatory suppression, a technique known to prevent the use of articulatory rehearsal (for an overview, see Table 2 in Cowan, 2001).

If this limit does indeed arise from the capacity limit of a domain-general storage device, then one should be able to demonstrate a fixed capacity limit across different domains of working memory. For example, if one is trying to maintain visual colors and spoken digits at the same time, one should find a limit at four items in total, such as three colors plus one spoken digit. It is important to note that such a trade-off in memory capacity across domains would not be expected if only domain-specific maintenance mechanisms would exist because, in that case, the digits would be stored in the verbal subsystem and the colors in the visuospatial subsystems, with very little influence from one subsystem on another because they are supposed to operate independently from attention and independently from each other. A constant capacity across domains was observed by Saults and Cowan (2007). Adults were able to maintain about four visual items or, when it was combined memory for spoken digits, four items in total (e.g., three colors plus one digit). Other studies also showed that verbal and visuospatial memory tasks interfere with each other (e.g., Morey and Cowan, 2004, 2005), suggesting that there is indeed a domain-general storage faculty in working memory. In the model of Cowan, the focus of attention would serve this role.

If the domain-general storage device is indeed closely related to attention, then one should observe that maintenance of information in this device is disrupted by other attention-demanding distractions that do not necessarily require maintaining some information, regardless of the specific domain to which that information pertains. Accordingly, researchers have shown that memory for visual arrays is disrupted by the requirement to identify tones that are presented to participants while they are trying to maintain the visual array (Morey and Bieler, 2012; Stevanovski and Jolicoeur, 2007). Similarly, Chen and Cowan (2009) have demonstrated that memory for spoken lists is disrupted by performing a simple three-choice visual reaction time task.

The question of whether concurrent attention-demanding activities disrupt ongoing maintenance activities, across the different domains of working memory, has been addressed explicitly within the framework of the time-based resource sharing model of working memory (TBRS, Barrouillet et al., 2004, 2007, 2011). According to this model, both processing and storage rely on attention. Attention being a limited-capacity resource has to be shared between the two main functions of working memory that are processing and storage. Next, the model assumed that, while attention is focused on information, it activates that information, but when attention is switched away from information, the memory traces of that information decay over time. In order to fight against this time-based forgetting, one needs to bring the information back into the focus of attention so that the memory traces get reactivated (see also Cowan, 1995). Importantly, as the TBRS model assumes that the focus of attention can only be on one element at a time, it cannot process and store information at the same time. This means that, while attention is captured by a processing task, it is not available for maintaining information and thus, information can get lost. Thus, the TBRS model predicts that as the proportion of time during which attention is captured by a processing task gets bigger, more information will get lost with poorer recall performance as a result. This proportion of time is called cognitive load.

To test this, new computer-paced complex span tasks were created. Complex span tasks require the retention of a series of items while concurrently performing a processing task and were developed by researchers assuming that any good measure of working memory should involve both processing and storage activities in order to capture the essential dual function of working memory. For example, Daneman and Carpenter (1980) created the reading span task that combines sentence verification with memory for series words, Case et al. (1982) created the counting span that combines counting dots with memory for series of numbers, and Turner and Engle (1989) created the operation span that combines solving math problems with memory for words. It has been shown that scores in complex span tasks have larger and more consistent correlations with higher order cognition than scores in simple span tasks that only require maintenance of information (e.g., Ackerman et al., 2005; Daneman and Carpenter, 1980; Engle et al., 1999).

Using similar kinds of tasks in which the pace of processing was imposed by the computer, Barrouillet and colleagues showed that recall performance is a linear function of the cognitive load of concurrent processing when processing and storage pertain to the same domain, either both verbal (e.g., Barrouillet et al., 2004, 2007, 2011) or both visuospatial (Vergauwe et al., 2009). Importantly, however, increasing the cognitive load of concurrent processing also disrupted maintenance for information that pertained to another domain of working memory: less letters were recalled when the cognitive load of a concurrent task consisting in judging spatial configurations increased, and less spatial locations were recalled when the cognitive load of a concurrent task consisting in judging words increased (Vergauwe et al., 2010; Vergauwe et al., 2012). This shows maintenance of information is disrupted by other attention-demanding distractions that do not necessarily require maintaining some information, regardless of the specific domain to which that information pertains.

As noted before, the initial notion within the WMG tradition was that in order to test the capability of the working memory system, both storage and processing had to be tied up

(Daneman and Carpenter, 1980; Case et al., 1982). Accordingly, complex span tasks were constructed in the aim of understanding individual and developmental differences in cognition and it was shown that these measures correlate robustly with measures of cognitive ability, much more than simple span measures (e.g., Daneman and Merikle, 1996), even when the storage and processing tasks come from different cognitive domains, such as spatial versus verbal domains (e.g., Kane et al., 2004: Lépine et al., 2005). However, an alternative interpretation of this set of findings is that one must tap attention-demanding processes to observe strong correlations with ability, and the processing task prevents rehearsal processes that otherwise would circumvent attention. Consequently, a single task can correlate well with cognitive ability when rehearsal is impossible. A good example is running span, in which a list of items is presented that is difficult to rehearse because the list length is not known in advance to the participant. With such a procedure, useful rehearsal is difficult or impossible (e.g., Hockey, 1973) and correlations with cognitive aptitudes are still very high despite the absence of separate storage and processing tasks (e.g., Cowan et al., 2005; Broadway and Engle, 2010).

Taken together, within the WMG tradition, research has resulted in proposing a domain-general maintenance mechanism that relies on attention. As such, within the WMG tradition, the answer to our question would be that information is maintained over short periods of time by focusing attention on the information to be maintained so that it gets reactivated over and over again. Thus, when one tries to maintain a phone number, one would use attentional refreshing, which consists in very briefly rethinking of the digits without the need to articulate them. Thus, it seems that the different traditions have a different answer to our question of how information is maintained over a brief period of time. However, as mentioned before, these views can be quite compatible.

Two Levels for Maintaining Information in Working Memory

A rather straightforward view to this debate would be to enforce the initial idea of Baddeley and Hitch (1974) according to which there is a central and a peripheral level in working memory, each with their own way of functioning independently from each other. In this idea, there would be a domain-general mechanism of storage that relies heavily on attention, that can be applied to maintain all kinds of information and that is disrupted by any concurrent activity insofar this activity requires attention for its execution. Although Baddeley (1986) omitted this level of storage in the interest of parsimony, he has more recently seen the need to revive such a notion in the form of the episodic buffer (Baddeley, 2000), which can include binding between different sorts of codes and served a function similar to the focus of attention of Cowan (1988). Next to this attentional refreshing, there would be peripheral maintenance mechanisms that act independently from attention, that can only be applied to a specific kind of information, and that are only disrupted by concurrent activities that involve information that is alike. Cowan's (1988) activated portion of LTM included interference on the basis of similarity to account for the same kinds of dissociations that Baddeley and Hitch accounted for with the phonological and visuospatial stores.

In line with the idea of central and peripheral levels in working memory, recent studies have shown that verbal material can indeed benefit from two independent mechanisms that operate jointly for maintenance (Camos et al., 2009; Hudjetz and Oberauer, 2007). Interestingly, Camos et al. (2011) showed that adults can adaptively choose between the two mechanisms: when they try to maintain verbal information that is phonologically very much alike, they prefer the attentional refreshing mechanism; when less attention is available, they favor articulatory rehearsal. While several studies have shown the existence of two separate mechanisms for maintaining verbal information, it appears very difficult to demonstrate the existence of a maintenance mechanism for visuospatial material that operates outside the focus of attention (e.g., Morey and Bieler, 2012; Rudkin et al., 2007; Vergauwe et al., 2009).

To conclude, the general way to maintain information over a short period of time seems to be by bringing it back into the focus of attention over and over again so that it gets reactivated instead of forgotten. For verbal material, such as a phone number, people have an extra mechanism available that consists in articulatory rehearsal, probably because this kind of information can be mapped directly onto a familiar spoken response (Baddeley and Larsen, 2007). Although working memory is relatively limited in capability and serves as a kind of bottleneck to what the human mind can accomplish, it does allow a number of strategic work-arounds (chunking, rehearsal, and refreshing) that underlie the awesome ability of humans to solve problems and create new things.

Abstract

'Short-term memory' refers to a number of systems, with limited capacities, which secure the temporary (in the range of seconds) retention of a variety of materials. Short-term memory systems are distinct from the more peripheral and short-lasting components of echoic memory for auditory stimuli, and iconic memory for visual stimuli. The three more extensively investigated short-term memory systems include: a phonological component, concerned with the retention of verbal material; a visual component, involved in recognition memory for objects; and a spatial component, retaining information about location. The general functional architecture of short-term memory includes a store and a rehearsal process, which preserves the temporary trace. These three retention systems are functionally independent, have discrete neural correlates in the association cortical areas, and may be selectively disrupted by brain damage. Phonological short-term memory is a mainly left-hemisphere-based system, including the posterior–inferior parietal (store component), and premotor (rehearsal component) regions. Memory for spatial location is a mainly right-hemisphere-based system, comprising the association occipital, posterior parietal, and dorsolateral frontal cortices ('dorsal visual stream'). Visual recognition memory for objects is associated with a network including the association occipital, temporal, and frontal cortices ('ventral visual stream'), possibly with a greater contribution from the left hemisphere. Short-term memory systems, in addition to supporting temporary retention for a variety of purposes, participate in the long-term learning of new information. One such case is the acquisition of new vocabulary in native or second language by children and adults.

Short-Term Memory

'Short-term memory' refers to a number of systems with limited capacity (in the verbal domain, roughly the 'magical' number 7 ± 2 items, see Miller, 1956), concerned with the temporary (in the range of seconds) retention of a variety of materials. 'Short-term memory' is separate from more peripheral retention systems, which store material for a shorter amount of time, in a format that is closer to the physical features of the stimulus: acoustical echoic, and visual iconic memory. Current knowledge of the functional and anatomical organization of short-term memory in humans, and its role in cognition, is presented, drawing data from three main sources of evidence: (1) behavioral studies in neurologically unimpaired individuals and in brain-injured patients with selective deficits of immediate retention; (2) correlations between the anatomical localization of the cerebral lesion and the short-term memory disorder of brain-damaged patients; and (3) correlations between the activation of specific cerebral areas and the execution of tasks assessing short-term retention in healthy participants. The two more extensively investigated aspects of short-term memory are considered: verbal and visuospatial. 'Short-term memory' is closely related to the concept of 'working memory.' The present article focuses on the 'storage' and 'rehearsal' components of the system, rather than on the cognitive operations and executive functions currently associated with 'working memory.' However, the section devoted to the uses of short-term memory illustrates some working aspects of short-term retention.

Historical Origin of the Construct 'Short-Term Memory'

Suggestions of a distinction between two types of memory, one concerned with temporary retention, and the other having the function of a storehouse for materials, which have been laid out of sight, date back at least to John Locke's *An Essay Concerning Human Understanding* (1690). In 1895, in his *Principles of Psychology*, William James revived the distinction, suggesting the existence of a limited-capacity 'Primary Memory,' embracing the present and the immediate past, and subserving consciousness. Psychological research in the nineteenth century and in the first half of the twentieth century was, however, mainly concerned with the diverse factors affecting learning and retention, in the context of a basically unitary view of human memory. It was only in the 1950s that short-term memory became the object of systematic behavioral studies in neurologically unimpaired participants. In the late 1960s, the fractionation of human memory into a short- and a long-term system became a current view (Atkinson and Shiffrin, 1968; Figure 1).

Functional Architecture of Short-Term Memory

Evidence from Unimpaired Participants

Phonological Short-Term Memory

Three main behavioral phenomena suggest the existence of a discrete limited-capacity system, concerned with short-term retention. (1) Accuracy in recalling a short list of stimuli (e.g., trigrams of consonants or of words) decreases dramatically in a few seconds if the participants' repetition of the memory material (rehearsal) is prevented by a verbal distracting activity, such as counting backward by threes. (2) In immediate serial recall of verbal material (memory span), the participants' repetition performance is limited to about 5–7 items (i.e., the above-mentioned 'magical' number seven). Recall is affected by factors such as phonological similarity and word length: lists of phonologically dissimilar items are recalled better than lists of similar items (phonological similarity effect); lists of short words are recalled better than lists of long words (word length effect). (3) In the immediate free recall of a long sequence of

Figure 1 The two-component serial memory model of Atkinson and Shiffrin (1968).

events, such as 15–30 words, exceeding the participants' immediate span, the final five to six stimuli of the list are recalled better that the preceding ones. This 'recency effect' vanishes after a few seconds of distracting activity, and is minimally affected by factors such as age, rate of presentation of the stimuli, and word frequency.

These empirical observations illustrate the main characteristics of 'short-term memory': a retention system with limited capacity, where rapid forgetting occurs, in the time range of seconds, due to interference and temporal decay of the memory trace. Forgetting may be prevented through rehearsal. Material stored in short-term memory has a specific representational format, which, in the case of the extensively investigated verbal domain, involves phonological codes, separately from lexical–semantic representations stored in long-term memory. Each of the three above-mentioned phenomena (short-term forgetting, immediate memory span, and free recall) subsequently proved to be considerably more complex than initially thought. They were also interpreted as compatible with a unitary, single-system, view of human memory. This account ran into difficulties, however, mainly on the basis of neuropsychological evidence.

The functional architecture of phonological short-term memory has been investigated in detail using effects that break down storage and rehearsal subcomponents. The effect of phonological similarity, whereby immediate serial recall of auditory and visual verbal material is poorer for sequences of phonologically similar stimuli than for dissimilar ones, reflects the coding that takes place in the phonological short-term store. The effect of word length, whereby the immediate serial recall of auditory and visual verbal material is poorer for sequences of long words than for short ones, is held to reflect the activity of the process of rehearsal, abolished by 'articulatory suppression,' i.e., a continuous uttering of an irrelevant speech sound. Suppression, while disrupting rehearsal, also reduces immediate memory performance in span tasks. The interaction between phonological similarity, input modality, and articulatory suppression, with suppression abolishing phonological similarity only when the stimuli are presented visually, suggests that rehearsal participates in the process of conveying visual verbal material to the phonological short-term store. Finally, some phonological judgments (such as rhyme and stress assignment) are held to involve the articulatory components of rehearsal, because the performance of neurologically unimpaired participants is selectively impaired by suppression.

Also lexical–semantic representations contribute to immediate retention, particularly in immediate serial recall (i.e., span), which is the task most frequently used in order to assess short-term memory performance. It has long been known that immediate memory span is better for words than for nonwords, namely letter strings which do not possess a preexisting representation in the lexicon (effect of 'lexicality'). Also, high frequency, and imaginable/concrete words are better recalled than low frequency, abstract words. The effects of semantic relatedness or similarity are more complex, with increase or decrease of recall performance having been reported.

Visual and Spatial Short-Term Memory

In the nonverbal domain a similar distinction is drawn between visual (for objects) and spatial (for locations) short- and long-term memory systems, with the relevant representational formats being in terms of shape or spatial position of the stimulus. These systems have a limited capacity of about 3–4 items, which can be retained in the range of seconds (Zimmer, 2008). Also in the visuospatial domain, similarity, recency, and interference effects have been observed. Visual and spatial short-term memories are likely to comprise storage and rehearsal (pictorial and spatial) components. In the case of spatial locations, rehearsal may include spatial attentional mechanisms, maintaining the encoded position of the stimulus in a spatial reference frame (e.g., egocentric), as well as planned movements (e.g., ocular, manual reaching, locomotion) toward the position of the target.

Other Domains: Tactile and Olfactory Short-Term Memory

Other sensory domains have been much less investigated, as compared with visuospatial and auditory-verbal (phonological) short-term memory. Accordingly, less definite conclusions can be drawn. In the tactile/haptic domain it appears that different systems support short- and long-lasting retention, with a distinction broadly similar to that found for the phonological and visuospatial short-term memory systems (Gallace and Spence, 2009). Also for olfactory memory, a distinction between short-term and long-term memory appears to be a valuable framework (White, 2009).

Evidence from Brain-Injured Patients

Studies in patients with localized brain damage provide evidence that supports the independence of short- and

long-term memory systems, conjuring up a double dissociation of deficits. In patients with 'global amnesia,' which may be characterized as a selective impairment of the declarative or explicit component of long-term memory, verbal and visuo-spatial short-term memory are unimpaired: immediate serial span, the recency effect in immediate free recall, and short-term forgetting are within normal limits. Immediate retention may, however, depend on long-term memory when the material to be memorized exceeds the limited capacity of short-term memory, is difficult to rehearse, and rehearsal is prevented, or attention is diverted (Jeneson and Squire, 2011). This functional dissociation suggests a serial organization of the two systems, with temporary retention being a necessary condition for long-term storage. Since the late 1960s, selective impairments of short-term memory have been reported (Baddeley et al., 2002; Vallar, 2006). The more extensively investigated area concerns auditory-verbal (phonological) short-term memory.

Selective Deficits of Phonological Short-Term Memory

The pattern of impairment. These patients show a disproportionate reduction of the auditory-verbal span to an average of less than three items (digits, letters, or words); the recency effect in immediate free recall of auditorily presented lists of words is abolished; short-term forgetting is abnormally rapid. The disorder is modality-specific, with the level of performance being better when the material is presented visually (Figure 2). This input-related dissociation has two main implications: (1) discrete phonological and visual short-term memory components exist; (2) in the input–output processing chain, the phonological short-term store should be envisaged as an input system, rather than as an output buffer store. This fractionation argues against a monolithic view of the system as a single store, which is amodal, namely: not specific for the different sensory modalities, as the model shown in Figure 1. Additional support to this input locus of the system comes from the observation that, in some of these patients, speech production is entirely preserved. Most patients exhibit the detrimental effect of phonological similarity with auditory presentation in span tasks. This is in line with the view that auditory information still gains access to a phonological code, which provides a main contribution to residual immediate retention, in spite of the damage to the phonological short-term store/rehearsal system. More generally, these findings are in line with the view that auditory material has an automatic access to phonological short-term storage, which is a robust process, infrequently entirely disrupted by brain damage. With visual presentation, these patients do not recode phonologically the to-be-recalled information, and there is some evidence for visual coding and retention to occur, in a visual short-term store (see Figure 4). The effect of word length is absent, and this suggests the lack of use or damage to the process of rehearsal.

The role of lexical–semantic long-term memory representations in residual span performance. The residual span performance of patients with defective phonological memory is likely to be supported by lexical–semantic codes, as that of neurologically

Figure 2 Short-term forgetting of a single letter by left-brain-damaged patient PV, after 3–15 s of delay filled by arithmetic distracting activity. With an auditory input, dramatic forgetting occurred within a few seconds. In the visual modality, the patient's performance was at ceiling. Immediate recall was fully accurate in both input modalities, ruling out perceptual and response-related deficits, differently from the short-term memory disorder. Data from Basso, A., Spinnler, H., Vallar, G., Zanobio, M.E., 1982. Left hemisphere damage and selective impairment of auditory-verbal short-term memory. Neuropsychologia 20, 263–274.

unimpaired participants. In a meta analysis of the auditory immediate serial recall performance of 25 patients with a defective phonological short-term memory, digit span is 2.38 (range 1–3.6), letter span 1.79 (range 1–2.5), and word span 2.00 (range 1.05), with the differences between the three types of stimuli being significant (Baddeley et al., 2002). The better serial recall of words indicates an effect of the lexicality of the stimuli. Conversely, patients with semantic dementia may show a reduction of such an effect in immediate serial recall, while showing comparable effects of phonological similarity (Jefferies et al., 2008).

Phonological short-term memory and long-term learning. Patients with defective phonological short-term memory may show unimpaired long-term verbal (Figure 3), and visuospatial learning. This observation further corroborates the complete independence of short- and long-term memory systems, but is incompatible with a serial organization – in which defective short-term memory systematically entails a long-term memory impairment, as predicted by serial models, such as the one shown in Figure 1 – suggesting a parallel architecture instead. After early perceptual analysis, information may enter short- or long-term memory, either of which may be selectively disrupted by brain damage. However, the learning abilities of these patients are dramatically impaired when the phonological material to be learned does not possess preexisting lexical–semantic representations in long-term memory. This is the case of pronounceable meaningless sequences of letters, such as nonwords, or words of a language unknown to the participant (Figure 3). This deficit of phonological learning indicates that, within a specific representational domain, temporary retention in short-term memory is necessary for a stable long-term learning and acquisition, as predicted by serial models. These findings also suggest interactions between short- and long-term memory systems, with the role of the latter supporting also immediate retention and learning, when preexisting representations of the stimulus are stored in the brain, such as in the case of words known by the participant.

Verbal rehearsal. The process of rehearsal has been traditionally described as an activity that, through rote repetition, refreshes the short-term memory trace, preventing its decay. The precise characteristics of rehearsal have been elucidated in more detail in recent years, particularly in the domain of phonological memory. Rehearsal may be conceived in terms of the recoding of the memory trace from input (auditory-verbal) to output-related (articulatory) representations and vice versa (Figure 4). More specifically, rehearsal of verbal material has long been regarded as 'articulatory' in nature, involving output-related verbal processes – such as the motor programing of speech production in a phonological assembly system or output buffer – the actual articulation of the material to be rehearsed (subvocal rehearsal), or both. Anarthric subjects, who are unable to utter any articulated speech sound, due to congenital disorders or brain damage acquired in adult age, may, nonetheless, show a preserved immediate memory, including verbal rehearsal. These patients have cerebral lesions involving the motor cortex or the descending efferent pathways, directed to neurons in the brainstem, which control the articulatory musculature. This is therefore not necessary for the operation of rehearsal, which should be conceived as a 'central'

Figure 3 Word (a) and nonword (b) paired-associate learning by patient PV and matched healthy control participants (C), with auditory presentation. The patient's performance was within the normal range with native language (Italian) words, dramatically defective with unfamiliar nonwords (Russian words transliterated into Italian). Data from Baddeley, A.D., Papagno, C., Vallar, G., 1988. When long-term learning depends on short-term storage. Journal of Memory and Language 27, 586–595.

process, not requiring any peripheral muscular activity. Conversely, brain-damaged patients with a selective impairment of rehearsal, due to lesions involving the left premotor cortex, show a defective immediate verbal span, as do patients with damage to the phonological short-term store. Both components of phonological memory contribute to immediate recall, with the phonological store providing the main retention capacity. The ability to perform phonological judgments is disrupted, however, by damage to the rehearsal process, rather

Figure 4 An anatomofunctional multicomponent model of phonological short-term memory (Vallar, 2006).

than to the phonological store. By contrast, a defective rehearsal leaves the recency effect in immediate free recall of auditory lists of words largely unimpaired. This recency effect is severely reduced or absent in patients with damage to the phonological short-term store, which is the main functional component contributing to it.

Orthographic-to-phonological recoding. Patients with defective phonological short-term memory have preserved grapheme-to-phoneme conversion skills, being able, for instance, to read aloud nonwords, namely sequences of letters that do not possess a lexical entry. Patients unable to articulate speech, due to bilateral damage selectively involving the motor cortex, may show a selective impairment of phonological recoding, with the phonological short-term store and rehearsal components being preserved.

Selective Deficits of Spatial and Visual Short-Term Memory

Brain-injured patients may show deficits of short-term retention in the visual or in the spatial domain, even though these patterns of impairment have been explored less extensively than the phonological disorder.

Deficits of spatial short-term memory. Immediate retention of short sequences of spatial locations, as assessed by a block-tapping task (a spatial analogue of digit span), may be selectively defective, with verbal and visual memory being unaffected, in both their short- and long-term components. Spatial long-term learning, assessed using a block-tapping test with a limited number of familiar positions (i.e., 9), may also be preserved. The imaginal deficit of right-brain-damaged patients with left spatial neglect (i.e., the patients' impairment to recollect the left-hand side of visuospatial images, retrieved from long-term memory) may be interpreted in terms of a unilateral disorder of visuospatial short-term memory. More generally, deficits of visuospatial short-term memory may contribute to a number of manifestations of the neglect syndrome: patients may fail to keep track of the explored positions in visual search tasks, revisiting previously explored targets. However, patients with left spatial neglect may show no deficits of visuospatial short-term memory: accordingly, the impairment of this immediate retention system, while possibly contributing to the manifestations of visuospatial neglect, and shaping them, does not appear to be a core component of the syndrome.

Deficits of visual short-term memory. In other brain-damaged patients, the deficit may involve the visual (shape) component of short-term memory, with spatial short-term memory being preserved. Impairments in the short-term visual recognition of unfamiliar faces, objects, voices, and colors have also been described. The disorder of patients with defective visual imagery (as assessed, for instance, by tasks requiring color or size comparisons) may be interpreted in terms of an impaired visual short-term memory store. A deficit of visual short-term memory may also disrupt long-term learning of unfamiliar nonverbal material, as assessed by recognition memory for unfamiliar faces and objects. This extends to the visual domain the conclusion that long-term acquisition requires short-term storage.

The Uses of Short-Term Memory

Is there a use for a system providing the temporary retention of a limited amount of stimuli, besides infrequent situations such as the following? A friend tells us an unfamiliar 8-digit number, which we have to dial on a telephone placed on the other side of a large street and we have no paper and pencil to write it down. The answer is positive. Short-term retention contributes to the stable acquisition of new information in long-term memory. More specifically, phonological short-term memory plays an important role in learning new vocabulary. It also participates in the processes of speech comprehension and production.

Long-Term Learning

The observation that patients with defective auditory-verbal span are impaired in learning unfamiliar pronounceable letter sequences gives rise to the possibility that phonological memory may contribute to a relevant aspect of language development, the acquisition of vocabulary (Figure 3). Similarly, individuals with a developmental deficit of phonological memory are impaired in vocabulary acquisition and in nonword learning. Individuals with a congenital cognitive impairment, such as Down's syndrome, provide an opposite pattern, when their deficit spares phonological short-term memory: acquisition of vocabulary, foreign languages, and

nonword learning are also preserved. Converging evidence from different populations supports this view. Correlational studies in children have shown that the capacity of phonological memory is a main predictor of the subsequent acquisition of vocabulary, both in the native, and in a second language. In normal adult participants, the variables that disrupt immediate memory span (phonological similarity, item length, and articulatory suppression) also impair the acquisition of nonwords. Polyglots have a greater capacity of phonological memory, compared to nonpolyglots, and a better ability to learn novel words. Phonological short-term memory may be considered as a learning device for the acquisition of novel phonological representations, and the building up of the phonological lexicon. A few observations in brain-damaged patients suggest a similar role for visuospatial short-term memory in the acquisition of new visual information, such as unfamiliar faces and objects.

Language Processing

The idea that short-term retention contributes to speech comprehension dates back to the 1960s. Phonological memory may withhold incoming auditory-verbal strings, while syntactic and lexical–semantic analyses are being performed. Patients with defective phonological memory show a preserved comprehension of individual words, as well as of many sentential materials, and a normal ability to decide whether or not sentences are grammatically correct. This may reflect, on the one hand, the operation of on-line lexical–semantic processes, heuristics and pragmatics, and, on the other, the complete independence of syntactic and lexical–semantic processes from phonological memory. Patients are, however, impaired by 'complex' sentences, where 'complexity' may refer to a number of nonmutually exclusive factors, such as a high speed of material presentation, which prevents the immediate build-up of an unambiguous cognitive representation; word order conveying meaning-crucial information (e.g., in sentences in which a semantic anomaly is introduced by a change in the linear arrangement of words: "The world divides the equator into two hemispheres, the southern and the northern"; the more complex sections of the Token Test, in which commands such as "touch the green big square and the small yellow circle" are given to participants); syntactic complexity, and extralinguistic presuppositions biasing the interpretation of the spoken message. Under these conditions, adequate interpretation may require backtracking to the verbatim (phonological) representation of the sentence, temporarily held in phonological memory. This provides a 'backup' or 'mnemonic window' resource for performing supplementary cognitive operations, necessary for comprehension.

Neurofunctional Architecture of Short-Term Memory

Phonological Short-Term Memory

Anatomoclinical correlation studies in brain-damaged patients with a selective impairment of auditory-verbal span indicate that the inferior parietal lobule (supramarginal gyrus) of the left hemisphere, at the temporoparietal junction, represents the main neural correlate of the 'store' component of phonological short-term memory (Vallar, 2006). The frontal premotor regions in the left hemisphere and other structures such as the insula are the major neural correlates of the 'rehearsal' component, even though the available anatomoclinical data are more limited (Figure 3).

Functional neuroimaging studies in normal participants concur with this pathological evidence, to suggest a left-hemisphere-based network. Activation in the left supramarginal gyrus (Brodmann's area (BA) 40) is associated with the 'store' component of short-term phonological memory, activation in the left frontal premotor BA 44 (Broca's area) and BA 6, and in the left insula, with the 'rehearsal' component (Paulesu et al., 1996). In these studies, in line with the behavioral evidence from unimpaired participants and brain-damaged patients, an immediate verbal span task activates both the inferior parietal region (phonological short-term store) and the premotor cortex (rehearsal process) in the left hemisphere. Conversely, rhyme judgments selectively activate the left premotor regions, whose damage, in turn, disrupts the patients' ability to perform this task. These activation and lesion-based data support, from an anatomofunctional perspective, the behavioral distinction between a 'storage' component and a 'rehearsal process' in phonological short-term memory. Furthermore, they qualify 'rehearsal' as a process making use of components (the 'phonological output buffer' of Figure 4) also concerned with the planning (i.e., programing in the left premotor cortex) of articulated speech. Seen in this perspective, phonological memory may be regarded as a component of the language system. Meta analyses of imaging studies in unimpaired participants involved in tasks requiring immediate retention of verbal material support a major contribution from the left hemisphere, including also subcortical structures (thalamus and basal ganglia); right hemisphere regions are also involved. However, when the retention task becomes more complex, with greater executive demands, the hemispheric asymmetry is no longer present (Wager and Smith, 2003).

Visual and Spatial Short-Term Memory

Studies in brain-damaged patients suggest an association between damage to the right hemisphere (and, to a lesser extent, to the left hemisphere) and defective short-term memory for spatial locations, with single items, or sequences of stimuli. There is also some, although less definite, evidence suggesting that damage to the posterior regions of the left hemisphere brings about disorders of visual short-term memory, such as defective immediate retention of sequences of visual stimuli (e.g., lines), and impaired recognition of more than one visual stimulus at a time (defective simultaneous form perception) (Baddeley et al., 2002).

Neuroimaging activation studies in humans support the distinction between primarily spatial (a location, a 'where' component) and visual (object) short-term memory systems (Wager and Smith, 2003; Zimmer, 2008). The main neural correlates of spatial memory for locations include the occipital extrastriate, posterior parietal, dorsolateral premotor and prefrontal cortices. Short-term visual object recognition

memory is associated with activations in a network including the occipital extrastriate, temporal, and ventrolateral premotor and prefrontal cortices. The prefrontal components may also differ in the type of processes they perform: the ventrolateral component in maintenance and retrieval, the dorsolateral component in monitoring and more active processing. Right hemisphere areas (posterior parietal, premotor, and prefrontal) may play a more relevant role in spatial memory for locations. The left inferior-temporal cortex may be particularly involved in visual object short-term memory. These patterns of activation indicate an association of the 'dorsal visual stream' with spatial short-term memory for locations and of the 'ventral visual stream' with short-term visual recognition memory for objects, although their hemispheric lateralization is controversial.

Neurofunctional Models of Short-Term Memory

Before the late 1960s, the prevailing view was that memory is a unitary system. Its fractionation into subcomponents started with the short-term/long-term distinction, such as that of the functional model of Atkinson and Shiffrin (1968), shown in Figure 1. In the following years, multicomponent models of memory were further developed, including subsystems both within long- and within short-term memory. As for short-term memory, subcomponents such as those shown in Figure 4 were specified, in both their functional architecture and neural underpinnings, with a main distinction involving store vs rehearsal subsystems, for verbal, spatial, and object (visual) domains.

This multicomponent view went not unchallenged, due to a resurgence of basically unitary models of memory. One such model is shown in Figure 5 (Ricker et al., 2010). Short-term memory is conceived as a subset of long-term memory, activated by attention and executive processes. The relationship between attention and immediate retention has been a long-standing issue. A unitary position may readily account for the contribution of long-term memory systems to immediate retention, with memory performance in any given specific task resulting from the contribution of the activated neurofunctional subset. Also multicomponent models, however, are open to interactions with long-term memory systems, as the one shown in Figure 4. Furthermore, lesion data from brain-damaged patients suggest that specific cortical regions of the brain are involved in immediate retention. These may be well conceived as an activated subset of long-memory, but then the differences between the unitary and the multicomponential approaches become unclear. This issue is illustrated in Figure 5, in which the store and rehearsal components of short-term memory are shown as specific (both at the functional and the neural levels) activated subsets. In addition, the phonological short-term store is conceived as a passive and automatic system, which needs little attentional resources in order to operate, as also shown by the robustness of the detrimental effects of phonological similarity on immediate serial recall performance in a variety of pathological conditions, ranging from selective deficits of phonological memory (Vallar, 2006), to semantic dementia, transcortical sensory aphasia (Jefferies et al., 2008), and the disexecutive syndrome.

Figure 5 A functional model of short-term memory as a subset of long-term memory, temporarily activated by attentional and executive processes (Ricker et al., 2010). The figure shows the phonological short-term store and articulatory rehearsal components of short-term memory as activated subsets.

In sum, while immediate memory performance depends on the contribution of different resources (in the verbal domain, phonological, lexical–semantic; in the visual domain, perceptual primitives, stored representations of objects; in the spatial domain, egocentric and allocentric reference frames), this does not necessarily imply that the system is unitary. The specificity of the syndromes of defective short-term memory (phonological, spatial, and visual) both behaviorally, and in terms of neural correlates, supports the view that this retention system should be conceived as a set of independent, though related, components, interacting with long-term memory, and with executive, and attentional resources.

'Short-term' memory, as discussed and illustrated so far, overlaps in part with 'working' memory (Aben et al., 2012), with this close relationship having been set since the development of the first models in the later 1960s and early 1970s, distinguishing 'short-' vs 'long-term' storage systems (Atkinson and Shiffrin, 1968). As outlined in this article, 'short-term' memory comprises a number of storage components, and specifically dedicated rote rehearsal and recoding systems, which, in the case of phonological short-term memory, may also be conceived as components of the language system. 'Working memory,' conversely, includes a number of more controlled processes (elaborative rehearsal, coding decisions, and retrieval strategies) which operate on the content of the different 'short-term' stores. Seen in this perspective, 'short-term' memory stores, and dedicated rehearsal processes, could be considered as subcomponents of a 'working' memory system (Baddeley, 2012). 'Working' memory may be also seen as a set of specific executive and control processes (among other systems, e.g., the programing of complex action), which operate on material temporarily held in different limited-capacity 'short-term' stores, with the contribution of rote rehearsal processes. More generally, the 'working' memory processes may be conceived as components of an executive system, mainly based in the

prefrontal cortex, involved in setting up complex, purposeful, and organized behavior (Stuss and Knight, 2012).

Conclusion

Behavioral observations and neuroanatomical evidence from normal participants and brain-injured patients concur in suggesting that 'short-term memory' should be conceived as a multiple-component system with specific functional properties and discrete neural correlates. These systems secure the retention of a limited amount of material in the time range of seconds and contribute to relevant aspects of cognition, such as the long-term learning of novel material, of which no preexisting representations are stored and available. Short-term memory systems closely interact with long-term memory, executive, and attentional processes in supporting immediate retention performance.

Main short-term memory systems include verbal, visual (object), and spatial components, with store and rehearsal processes. The brain bases of short-term memory are mainly cortical regions: (1) a posterior parietal–dorsolateral frontal network for the verbal system, with a major role of the left hemisphere; (2) an occipital extrastriate-posterior parietal–dorsolateral frontal network for the spatial (location) system (dorsal stream), with a major role of the right hemisphere; and (3) an occipital extrastriate-temporofrontal network for the visual (object) system (ventral stream). These networks are largely distinct from those involved in long-term memory performance, which include the medial temporal lobe, diencephalic nuclei, and their connections.

Shrinking Cities

Robert Beauregard, Columbia University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Persistent population loss from cities around the world has given rise to a new research and policy initiatives meant to combat the consequences of depopulation. This new perspective replaces an earlier concern with urban decline while deemphasizing large-scale, commercial redevelopment projects as an antidote to the lack of growth. This article reviews the origins of the shrinking city idea and surveys the recent and continued depopulation of cities in the United States, Europe, and Asia. It then considers various policy responses that focus on addressing the twinned problems of abandoned housing and the reuse of once-occupied sites, often via efforts to make the city more environmentally sustainable. After discussing arguments for shifting city policy from the pursuit of growth to 'smaller is better,' the cases of Detroit (USA) and Leipzig (Germany) are discussed.

Through the centuries, the populations of cities and towns have expanded and contracted. Until the midtwentieth century, the overall trend was one of growth. Just after World War II, however, large cities (particularly those with manufacturing economies) began to shed residents, businesses, and jobs in alarming numbers. Certain of these cities, places like Cleveland and St. Louis in the United States, did so uninterrupted for decades. The preferred term for this condition was 'urban decline' (Beauregard, 2003). By the end of the century, however, urban living (at least in the United States) had become attractive once again and a new, less-freighted term was needed. Still losing residents, these cities were no longer 'declining,' they were 'shrinking.'

Origins

The term 'shrinking cities' became prominent around 2000 when a group of scholars applied the label to east German cities. The phrase echoed a 1980s discussion of declining industrial cities in the Ruhr area and received international publicity from a project – *Schrumpfende Stadte* – initiated by Philipp Oswalt (2005, 2006). That project gathered descriptions of such shrinking cities as Manchester (UK), Detroit (USA), and Halle/Leipzig (Germany) and produced reports, videos, books, and exhibitions. At approximately the same time, Karina Pallagst at the University of California: Berkeley organized a conference on the topic that launched the Shrinking Cities International Research Network (Martinez-Fernandez et al., 2012). These activities were soon followed by initiatives in Germany (e.g., the 5-year Shrink Smart research consortium funded by the European Union) and in the United States, notably the 'Defining the Future for America's Cities' conference in 2011 in Detroit under the auspices of The American Assembly at Columbia University (New York City) (Mallach, 2012a).

Additional attention was focused on shrinking cities in the United States by the National Vacant Properties Campaign (NVPC) (Leonard and Schilling, 2007). NVPC was later subsumed under the Center for Community Progress (CCP) in Washington, DC, and also gave rise to the Vacant Property Research Network. The CCP works with both governmental and nongovernmental stakeholders to 'reintegrate vacant, abandoned, and blighted properties into the economic and civic life of their communities.' Various pieces of legislation were introduced in Germany (e.g., Stadtumbau Ost) and the United States (e.g., the Neighborhood Stabilization Program of 2008) and this reinforced the belief that shrinking cities, if not qualitatively distinct from declining cities, had to be approached differently. By 2013, a robust network of international researchers and policy activists had emerged to share ideas across national and city boundaries.

Depopulation

Central to the shrinking city discussion is population loss. Undeniable was that while cities had cast off residents in the past, the losses after the 1950s were prevalent across certain types of cities, unprecedented in scale, and (most importantly) persistent. In the United States, substantial population loss from the older central cities began in the 1950s and reached its peak in the 1970s (Beauregard, 2009). During that decade, New York City had an unprecedented drop-off of 824 000 residents (10.4%) with no other city in the United States even close to matching that number – the city second in population loss, Chicago, had a decline of 362 000 residents (10.7%). Over two-thirds of the 50 largest cities lost population in the 1970s. Between 1950 and 1980, the large cities that shrunk experienced an average loss of 72 000 residents while between 1980 and 2000 that number decreased but was still a significant 50 000 people. Between 1950 and 2010, Flint (Michigan) became smaller by 61 000 residents (37%), while after 1990 New Orleans (Louisiana) declined in population by 29%, Cleveland (Ohio) by 18%, and Rochester (New York) by 11%. Urban decay, suburbanization, deteriorated public services, and racial conflict were key contributors to the out-migration of households. Plant closures in heavy manufacturing and the decentralization of light industry, initially to the suburbs but later from the northeast and Midwest regions to the south and west regions, further contributed to the diminishing attractiveness of these places.

In the United Kingdom, population loss was a serious problem beginning in the 1950s. Manchester's peak population occurred in 1931 while Birmingham peaked in 1951 and Sheffield in 1981 (Turok and Mykhnenko, 2007). Thereafter, they all lost residents with Manchester having a 47% decline, down 393 000 residents from 1931. In Europe, population loss from shrinking cities was in part a consequence of the devastation of World War II with industrial restructuring (particularly involving heavy manufacturing and coal mining) also influential. Central to the recent shrinking city phenomenon in Europe was the dissolution of the Soviet Union in 1989 and the breakdown of state socialism that led to a massive migration of people both from the low-wage Communist to high-wage Western countries and, within the postsocialist countries, from rural areas and small and medium-size cities to the major cities such as Prague (Mykhenenko and Turok, 2008; Wiechmann, 2008). The result was a landscape of urban shrinkage that mostly overlapped the areas where manufacturing had anchored the regional economy. An additional contributing factor was the drop in fertility rates below population replacement levels.

Outside the postsocialist world, and between 1970 and 2005, Torino lost 35% of its manufacturing jobs while Sheffield experienced a 74% decline, with corresponding population losses. Halle (Germany), Budapest (Hungary), Bytom (Poland), Torino (Italy), Donetsk (Ukraine), Glasgow (Scotland), and Murmansk (Russia) also shed large numbers of residents (Power et al., 2010). Bologna in Italy lost 24% of its population after 1971, Porto in Portugal fell 20% in population after 1981, and Murmansk in Russia lost a quarter of its residents in the 15 years prior to 2005. In cities where shipping and port activity declined, such as Marseilles (France) and Genoa (Italy), population losses followed. Compared with the United States, and speaking generally, depopulation was not severe, albeit with exceptions like Manchester in England.

Beyond Europe and Russia, former manufacturing cities and cities dependent on a particular industry (whether manufacturing such as steel or resource extraction such as coal mining) experienced a similar loss of residents. Sudbury in Canada, Mount Isa in Australia, Zhouzhuang in China, and Yubari in Japan are just a few of these shrinking cities. In Japan, demographic change has been a major factor in long-term shrinkage while economic instabilities have been more important as regards short-term shrinkage. Between 1990 and 2005, 30 of the 47 prefectures in Japan experienced depopulation. Cities with fewer than 200 000 residents were most prone to shrinkage with company towns such as Hitachi and Muroran particularly vulnerable. The exceptions were the medium-size cities located in the suburban ring of metropolitan areas. Overall, shrinking cities are most often found in declining industrial regions, although sprawl development and suburbanization can also be detrimental for city population growth and, as in the United States, often coincide with industrial restructuring.

While cities like Cleveland (Ohio) and Camden (New Jersey) in the United States and Manchester and Liverpool in the United Kingdom led the way in the period of urban decline, by the 1990s, cities in the United Kingdom had begun to rebound while those in the United States continued to cast off residents and jobs (Beauregard, 2009). In the United States, places like Boston (Massachusetts) and Washington, DC, suffered population losses prior to 1990 and prospered thereafter. Other cities – manufacturing centers with significant coastal or inland ports – continued to shrink. Pittsburgh, Detroit, Cleveland, St. Louis, Baltimore, Philadelphia, and Buffalo topped the list of big cities. Not only had these cities shed residents steadily from 1950 to 1990, they continued to do so after that time. Baltimore, for example, had a 22.5% net lost of residents from 1950 to 1990 and then another 11.5% decline (approximately 85 000 people) between 1990 and 2010. Of the medium-size and small cities, Flint (Michigan), Camden (New Jersey), Chester (Pennsylvania), Youngstown (Ohio), and Rochester (New York) have been the most prominent of those that have become smaller.

To the extent that the collapse of heavy manufacturing and resource extraction were main contributors to population loss (whether in the era of decline or shrinkage), the shrinking cities are concentrated in specific regions within these countries. The industrialized Ruhr area was the site of many of Germany's shrinking cities. In the United States, it was the Midwest region and parts of the northeast around the Great Lakes. And while the Midwest did not suffer an absolute population loss between 1950 and 2010, it grew slower than the west and south regions and went from having 29% of the country's total population to 22%. In Poland, cities in the coal mining and steel-making region of Silesia were particularly vulnerable. And, in England, the cities in the manufacturing and coal mining regions of the north were the major sites of urban shrinkage. In East Germany, the population went from 18.2 million residents in 1990 to 17.0 million in 2002 due to manufacturing decline and the reunification that enabled east Germans to chose where to live. Moreover, certain sparsely populated and agricultural or natural resource regions also lost population. These were areas like northern Finland, eastern Scotland, and northern Sweden.

Although many central cities in the United States have been shrinking, their metropolitan or urban regions have not. Since 1970, about 1 of 10 metropolitan areas have lost residents in any given census enumeration period, with most of them having only episodic rather than persistent losses. The metropolises of Buffalo (New York), Dayton (Ohio), Pittsburgh (Pennsylvania), and Youngstown (Ohio), however, have all been shrinking, as have their central cities. In about one-half of the instances of metropolitan depopulation, the overall population loss was solely a matter of central city population loss. As a generalization, suburban areas tend to grow in metropolitan areas of the United States even if their central cities do not. Nonetheless, a small number of shrinking metropolitan areas have experienced suburban population losses as well.

In Europe, conditions have been somewhat different. Over one-half of all functional urban regions (roughly equivalent to metropolitan areas of the United States) in the European Union had lost population between 1996 and 2001. Suburbanization, however, was less of a factor than deindustrialization. With suburbanization, the city's dominant city often loses residents, whereas industrial collapse coupled with German reunification and the demise of the Soviet Union has led to whole functional urban regions becoming smaller in population.

Overlapping the shrinking cities' phenomenon was the bursting of the housing bubble in 2008, a condition that occurred in numerous countries. During the real estate boom of the early to mid-2000s, with investment capital readily available, developers (and governments) built large residential communities and new towns. Inexpensive and easily obtainable home mortgages, heavy borrowing by homeowners against their home equity, exotic and untested mortgage instruments, speculative anticipation of property value appreciation, and unscrupulous lending practices fueled building activity. With many households having taken on mortgages that were financially untenable if the economy failed to grow rapidly, a bursting of the housing bubble was inevitable. Banks withdrew investment capital and large projects were halted in midconstruction. Mortgage foreclosures increased dramatically, particularly in older cities with weak housing markets but also in rapidly growing metropolitan areas like Phoenix in the United States (Immergluck, 2009). Cleveland and Detroit were particularly hard-hit, leading to further blight, abandonment, and population out-migration.

Shrinkage, then, was not just a product of manufacturing decline, suburbanization, or demographic collapse, but was also brought about by real estate speculation and unscrupulous lending practices. In Spain and Ireland, in the southwest region of the United States, and even in Inner Mongolia (where the government had built new towns), many real estate ventures simply collapsed, failing to attract homebuyers and essentially going into default. Ordos in Inner Mongolia and the Cheng-gong district in Kunming in the Yunnan province in China were two of the most prominent of these developments. These places earned the label 'ghost cities.' Even New York City felt the consequences of the 2008 economic recession with nearly 700 construction projects 'stalled' and thus empty in 2010.

Policy Response

Research and policy on the decline and adaptation of shrinking cities tends to focus on the significant problems posed by abandoned and derelict housing, thereby turning the shrinking city issue into a debate about distressed neighborhoods (Billitteri, 2010; Dewar and Thomas, 2013; Schilling and Mallach, 2012). All of the shrinking cities in the United States and Western Europe have experienced significant numbers of vacant and abandoned homes. (In Eastern Europe, depopulation has mainly reduced overcrowding.) Often clustered in specific (usually low-income and/or formerly industrial) neighborhoods, vacant and abandoned buildings pose health and fire hazards and detract significantly from the public image of the city and the potential reuse of the land on which these buildings sit. Numerous cities have responded with extensive housing demolition efforts, setting goals in the tens of thousands over a short time span. Baltimore (Maryland) in 2002, undertook to demolish 5000 houses per year over 5 years, hoping to reduce its stock of 40 000 vacant buildings. Philadelphia's Neighborhood Transformation Initiative, launched in 2001, demolished 14 000 abandoned buildings (Gurwitt, 2002). Despite such efforts, these shrinking cities still had large numbers of derelict and abandoned homes as residents continued to leave. Moreover, one less-than-desirable consequence of their efforts was block after block of vacant lots, often weed-strewn and unsightly.

In many of these cities, the local housing stock not only consisted of a high percentage of vacant and abandoned buildings but was also a target of speculators who bought properties cheaply in the hopes of taking in rents (without making any repairs or renovating them) or quickly selling them at a profit (Mallach, 2012b). Such speculation encouraged existing residents to sell, and they often then left the city. It also prevented the city government from taking control over these properties and sealing them to prevent vandalism and fires or managing demolition and subsequent clean-up of the site. Local governments were further constrained by the lack of efficient and effective legal tools to acquire and dispose of vacant properties.

To this end, a few, pioneering local governments began to experiment with new models of land banking that enable a central authority to acquire vacant properties before they are purchased by speculators (Mallach, 2004, 2012b). While cities such as Atlanta and St. Louis had chartered land banks in the 1970s and 1980s, more comprehensive land bank models emerged in the 2000s. In Michigan, a reform of municipal tax foreclosure laws gave county-level governments the ability to create the next generation of land banks. With these new powers, land banks could undertake a broader range of activities such as purchasing tax-delinquent abandoned properties, demolishing the buildings, and managing the subsequent reuse, sale to a private owner or transformation of the lot into a community garden. The most famous of these land banks in the United States is the Genesee County Land Bank Authority that took on the responsibility for managing Flint, Michigan's abandoned housing stock. Nevertheless, some local officials remain averse to demolishing usable properties and are hopeful that buyers can be found to inhabit them. This is seldom the case.

Demolition has also played a significant role in Europe for adapting to smaller populations (Bernt, 2009; Wiechmann and Pallagst, 2012). Many former East German cities made the removal of vacant buildings a major redevelopment goal. Of particular challenge in this regard has been the large, Communist-era, housing estates (such as Gruneau outside Leipzig) where ownership changes and out-migration resulted in buildings with little to no financial value. Approximately 8000 flats were demolished in Leipzig and another 7600 in Gruneau, with the latter aimed at reducing densities so that the estates could remain viable.

Housing demolition initiatives in the United States were done in the hope that either investors would then purchase the now-empty lots for new residential and commercial developments or community development corporations (CDCs) would acquire vacant lots for affordable housing or community gardens. By the 1990s, though, it was clear that most private investors had little interest in doing so while CDCs lacked the resources or organizational capacity. City officials and community groups began to grapple with two, harsh facts: first, their cities were unlikely to attract significant numbers of tax-paying and consumer-spending households or of businesses that could provide jobs and pay taxes to the local government and, second, that heavily subsidized, large-scale economic or real estate development projects were

unlikely to reenergize the local economy. Growth was not a presumable solution; stabilization was the more pragmatic goal.

The United States' situation differed from that in the United Kingdom and Germany. In the cities of the United Kingdom, demolition was meant to remove substandard housing and to build lower density housing on the now-vacant sites. As for Germany, Leipzig is an example of a city where demolition was used to balance supply and demand; by 2013, the city was beginning to repopulate its housing stock. And, in Eastern Europe much of the demolition was directed at derelict structures remaining from the socialist era.

Consequently, and primarily for the United States, a key difference between a declining city perspective and a shrinking city perspective was that city officials, community development leaders, and local elites began to talk about the possibility that their city would simply have to adapt to being smaller (Dewar et al., 2013). (By contrast, city policy in Leipzig was always about attracting new investment and expanding the population.) Leading the way in this discussion was Youngstown (Ohio) whose 2005 vision statement and citywide plan recognized that the city was unlikely to experience significant population growth and thus any planning for the future had to think in terms of less development than it previously had (Mock, 2011; Swope, 2006). Even in Youngstown, the mayor under whom the plan had been written maintained his public commitment to growth once the city had been stabilized. Most scholars, researchers, and policy analysts took the position that these cities had to 'think smaller.' Large-scale, ostensibly catalytic projects requiring major capital investment (and deep public subsidies) were viewed with a new skepticism. For elected officials and owners of downtown properties and businesses, such thinking went against their interests. It was difficult for them to imagine a smaller city that would also be prosperous.

For the 'smaller is better' advocates, having fewer residents with more vacant land and less dense development was an opportunity to become more sustainable (Krohe, 2011; Rugare and Schwarz, 2008). Detroit is reported to have 20 mi^2 of vacant land, almost all of which was once occupied by homes, factories, and stores. The vacant land could be used for community gardens, absorb rainwater, support small forests that could counteract air pollution, or be planted to provide noise buffers between residential neighborhoods and industrial areas. Large areas could be allowed to 'go wild' – back to nature – thus supporting birds and animals. Contaminated sites could be replanted with vegetation that 'cleaned' the soil. Buried streams could be 'day-lighted' to channel water run-off. Retention ponds could be built to divert storm water from the sewer system. Greenways – linear parks – could be fitted into the remaining urban fabric. By managing the vacant land, the city could become less dense in a way that fell between an 'urban' and a 'suburban' landscape while being ecologically sustainable.

A good example of this approach is "Reimagining a More Sustainable Cleveland," a project that began in 2007. Its goal was to devise strategies for making sustainable reuse of vacant properties, by positioning these sites within the city's larger, ecological processes. Of the many, community-initiated projects it funded were a vineyard, pocket parks, rain gardens, and neighborhood pathways. High on the list of goals were carbon sequestration, soil restoration, biodiversity, and heat island mitigation.

At the same time, elected officials and government administrators grapple with the problem of how to adapt the infrastructure and public services of the city to its smaller population. Local governments in the United States shrinking cities suffer from falling property values and declining tax revenues and yet have to maintain water mains, streets, schools, and fire stations that are overcapacity for the current population size. Cities do not shrink evenly with one area of the city emptying-out before another begins to lose residents and businesses. Rather, the shrinkage is geographically uneven, with areas only partially abandoned. This forces city governments to provide services in sparsely populated neighborhoods; that is, neighborhoods with fewer people than could be served by the existing infrastructure whether fire stations or sewer lines. One response is to withdraw services (e.g., close the elementary school), while another is to move from universal provision to a fee-for-service delivery model (e.g., having homes and businesses pay individually for the trash that they want removed).

Detroit

Scholars, activists, and practitioners working on shrinking city issues generally agree that stemming population loss, housing demolition, ecological reuse of vacant land, and infrastructure and public service resizing need to be addressed in a coordinated fashion; that is, from a planning and urban design perspective. The Youngstown master plan was a first effort, and in 2013 the Detroit government unveiled the most comprehensive of these endeavors, *Detroit Future City*. A product of the Detroit Works Project, and totally funded by philanthropies, it attempted to align the city's assets with its opportunities, essentially acknowledging the current situation of severe population and job loss and setting stability (not growth) as a goal. The plan further argued that the smaller population might be less important than the diversity of residents and the robustness of the job base. (Detroit still has jobs, but most of them are taken by workers who lived in the suburbs.) It proclaimed that "Detroit can be a vibrant city of 700 000 people or less if deliberate actions are taken to increase family wealth and the earning power of people who are now in poverty."

Detroit occupies a central position in the public debate about shrinking cities (Berkooz, 2010; Galster, 2012; Ryan, 2012). Not only has it experienced severe population loss, falling from a population of 1.85 million in 1950 to 713 000 in 2010, it is often touted as the city with the worst housing stock, the greatest expanse of vacant land, a history of dysfunctional local government, and the most devastated industrial landscape of any shrinking city in the country. A survey in 2009 recorded 33 000 abandoned homes and 90 000 vacant lots. With the decentralization of the automobile industry, the economic base of the city had collapsed. In the 1940s and continuing for decades, racial tensions and overt conflict led to the out-migration of many white households. Blocked from relocating to the suburbs, African–Americans subsequently became geographically concentrated in the city. Detroit became a predominately African–American city with a large proportion of poor people and a government struggling to manage public services and

avoid bankruptcy. In 2013, with fiscal insolvency imminent, the Michigan state government put Detroit in receivership and took control of the city's finances. Flint (Michigan) was already under state financial management.

One source of hope for Detroit, at least as reported in the popular media, was the influx of young artists in search of cheap housing and studio space (Herscher, 2012). A proposal to build a light-rail line from the central business district to the northern suburbs was intended to increase property values (and eventually tax revenues) along a major transportation corridor, but was later changed to a less expensive rapid-bus service. The city had earlier built new stadia for professional baseball and football teams downtown and was successful in attracting gambling casinos, with the latter becoming major contributors to the city's tax revenues. The impact of these large-scale efforts on the city's economy and its residents has been minimal. In 2013, poverty was still entrenched and the city's fiscal stability still elusive. Detroit also attracted photographers fascinated by the industrial devastation, collapsing homes, abandoned schools, and once-occupied but now-vacant lots. The resultant photographs were labeled 'ruins porn' and can be found all over the web.

Detroit was not alone among shrinking cities in the United States in undertaking ostensibly catalytic projects to bolster the local economy (thereby increasing job opportunities and encouraging capital investment) and retain existing residents while attracting new ones. Pittsburgh built new baseball and football stadia, expanded its convention center, and established a downtown arts district anchored by a museum and a symphonic hall. Philadelphia subsidized new residential development in areas where it had undertaken demolitions, launched a major initiative to revitalize the riverfront, transformed a former shipyard into an area of offices and residences, and provided support for expanding its museum district along one of its historic avenues. Washington, DC, built a new baseball stadium on its riverfront and slated the surrounding area for residential and commercial development. It also established a new office district behind its central rail station. With a thriving governmental sector attracting young people to the city, the government made every effort to support and publicize its gentrifying neighborhoods. In all instances, the leadership of these shrinking cities did not fully abandon the belief that large-scale investment would bring back prosperity. Even in cities with vast tracts of vacant and abandoned housing, city governments still adopted policies and distributed subsidies to enable private sector and nonprofit developers to build new housing.

Leipzig

The other side of the shrinking city narrative is occupied by Leipzig in the former East Germany, a city whose population dropped 7.0% (37 000 people) between 1989 and 2001 (Bontje, 2004; Power et al., 2010: pp. 107–129). Here, the focus of scholars and policymakers is not the devastation, but the ability of the German government, supported by European Union funding, to respond to shrinkage. Leipzig suffered both from industrial collapse and suburbanization and, as its population fell, high vacancy rates in the housing sector. Various governmental programs renovated existing housing, developed new uses for industrial buildings, turned vacant land into walking trails and linear parks, and built in-fill residential projects to stabilize neighborhoods. The government also supported development in the central business district with, among other projects, a new shopping mall in a modernized train station, a new building for its internationally recognized trade fair, and an expanded and enhanced airport. On the city's fringe, former coal mining sites were turned into recreational areas, initiatives that extended the German government's efforts in the 1990s to remediate and redevelop the Emscher River valley in the former industrial region of the Ruhr, an initiative that produced the well-known Emscher Landscape Park and Duisburg-Nord Landscape Park. European shrinking cities were less damaged by population loss and seemed better able to manage the consequences of depopulation.

Leipzig was not the only shrinking city in Europe engaged in various redevelopment and economic development initiatives to stem population loss, reenergize the local and regional economies, and make itself more competitive for capital investment. Bilbao in Spain became world-famous after the construction of its Guggenheim Museum designed by the famous architect Frank Gehrey. The museum boosted tourism and changed the image of this once-industrial city. Belfast in Ireland in the 1990s embarked on a regeneration of its mostly derelict and environmentally contaminated port area and established a science park to attract high-technology businesses. Waterfront regeneration, airport expansion, public transportation investments (e.g., a new metro in Bilbao), and technology parks as well as neighborhood renewal and new housing became the major tools for controlling shrinkage.

Conclusion

While New York, Shanghai, London, Sao Paulo, and Amman are struggling to attend to the problems of growth, other cities across the globe are devising policies and programs for managing depopulation. Faced with the prospect of minimal growth in the near-future, these cities can only hope to become smaller in a way that is less physically destructive, less harmful to existing residents, and environmentally sustainable. Even though these cities are only shrinking and not declining, a distinction more rhetoric than reality, they still have formidable challenges to overcome. One of the most daunting in the United States is the increasing poverty of the remaining residents. Hovering over this state of affairs, and unavoidable in 2013 as an economic recession lingered in most of these countries, was the prospect that conditions could worsen.

Sibling-Order Effects

Frank J Sulloway, University of California Berkeley, Berkeley, CA, USA

Abstract

Throughout much of the world, eldest children are privileged, socially and economically, over their younger siblings. For this reason, firstborns tend to exhibit greater filial loyalty compared with laterborns. Because sibling order is a proxy for individual differences in age, size, and status, it affects sibling strategies in competition for parental investment. Differences in sibling strategies in turn exert a modest influence on personality and social behavior, reflecting a Darwinian process by which brothers and sisters seek to reduce direct competition through the adoption of unique family niches. Eldest siblings, who typically occupy the niche of a surrogate parent, tend to be more conscientious, achievement oriented, and conforming to authority than are their younger siblings; whereas laterborns, who cultivate low-power strategies, are often more agreeable, open to experience, and extraverted in the sense of being fun-loving and excitement-seeking. These differences in personality are displayed in various historical trends, as laterborns have often championed radical revolutions and reform movements – including the Protestant Reformation, numerous political revolutions, and radical revolutions in science.

Historically, sibling order has influenced important aspects of social, economic, and political life, and it continues to do so today in many traditional societies. Discriminatory inheritance laws and customs about royal succession that favor firstborns and eldest sons are just two examples. Sibling-order effects have also been documented for a wide variety of behavioral tendencies, although the magnitude and causal interpretation of these effects have been subject to debate. In the Darwinian process of competing for parental favor, siblings often employ strategies that are shaped by order of birth within the family, and these strategies exert a lasting impact on personality. Radical revolutions are particularly likely to elicit differences in support by birth order. These behavioral patterns appear to be mediated by differences in personality as well as by differing degrees of identification with the family.

Social, Economic, and Political Consequences

Many societies – especially in past centuries and in non-Western parts of the world – have engaged in practices that favor one sibling position over another. For example, most traditional societies permit infanticide, especially when a child has a birth defect or when an immediately older infant is still breastfeeding. However, no society condones the killing of the elder of two siblings (Daly and Wilson, 1988). An extensive survey of birth order and its relationship to social behavior in 39 non-Western societies found that the birth of a first child typically increases the status of parents and stabilizes the marriage (Rosenblatt and Skoogberg, 1974). In addition, firstborns generally received more elaborate birth ceremonies, were given special privileges, and tended to exert authority over their younger siblings. In most of these 39 societies, firstborns maintained supremacy over their younger siblings even in adulthood. They also gained control of a greater share of parental property than laterborns, were more likely to become head of their local kin group, and tended to exert greater power in relationships with nonfamily members.

Previously, many Western societies employed sibling order as a means of deciding who inherits parental property or assumes political power. Primogeniture (the policy by which the eldest child or son automatically inherits property or political authority) was the most commonly employed mechanism, but other discriminatory inheritance practices have also been employed. For example, secondogeniture involves leaving the bulk of parental property to the second child or second son, and ultimogeniture involves leaving such property to the last-born or youngest son.

Most variations in inheritance practices by sibling order can be understood by considering the advantages that accrue from such policies, given local economic circumstances (Hrdy and Judge, 1993). For example, primogeniture has generally been practiced in societies where wealth is stable and based on limited land, and where talent does not matter much. Leaving the bulk of parental property to a single offspring avoids subdividing estates and hence reducing the social status of the family patronymic – something that was particularly important in past centuries among the landed aristocracy. However, in Renaissance Venice economic fortunes were generally based on speculative commerce rather than ownership of property, and parents typically subdivided their estates equally so as to maximize the chances of having one or more commercially successful offspring (Herlihy, 1977). Ultimogeniture is a policy often found in societies that impose high death taxes on property. This inheritance practice has the consequence of maximizing the interval between episodes of taxation, thus reducing the overall tax burden.

Even in societies employing inheritance systems that favor one sibling over others, parents have commonly provided more or less equally for their offspring by requiring the child who inherits the family estate to pay a compensatory amount to each sibling. Primogeniture and related practices did not always mean disinheritance – a common misassumption. In medieval and early modern times, however, primogeniture among the landed aristocracy did mean that some younger sons and daughters faced difficult economic and social prospects. Among the medieval Portuguese nobility, landless younger sons and daughters were significantly less likely to marry and to leave surviving offspring (Boone, 1986). Younger sons, for example, left 1.6 fewer children than did eldest sons.

Younger sons were also nine times more likely than eldest sons to father a child out of wedlock. Because they posed a serious threat to political stability in their own country, younger sons were channeled by the state into expansionist military campaigns in faraway places such as India, where they often died in battle or from disease. Similarly, the Crusades can be seen, in part, as a church-state response to this domestic danger (Duby, 1977). The surplus of landless younger daughters in the titled nobility was dealt with by sending them to nunneries.

Personality

Birth-order differences have long been claimed in the domain of personality, although these claims have remained controversial despite considerable research on this topic. Psychologists have investigated the consequences of birth order ever since Charles Darwin's cousin Francis Galton (1874) reported that eldest sons were overrepresented as members of the Royal Society. After breaking away from Sigmund Freud in 1910 to found a variant school of psychoanalysis, Alfred Adler (1927) focused on birth order in his own attempt to emphasize the importance of social factors in personality development. A secondborn, Adler considered firstborns to be 'power-hungry conservatives.' He characterized middleborns as competitive and lastborns as spoiled and lazy.

Since Adler speculated about birth order and its consequences for personality in 1927, psychologists have conducted more than 2000 studies on the subject. Critics of this extensive literature have argued that most of these studies are inadequately controlled for key covariates, such as social class and sibship size; that studies often conflict; and that birth-order differences in personality and IQ seem to have been overrated (Ernst and Angst, 1983). Meta-analysis – a technique for aggregating findings in order to increase statistical power and reliability – suggests a different conclusion. If we consider only those well-designed studies controlling for important background variables that covary with birth order and can introduce spurious cross-correlations, meta-analytic reviews reveal modest but consistent birth-order differences for a wide range of personality traits (Sulloway, 1995, 2010). For instance, firstborns are generally found to be more conscientious than laterborns, a difference that is exemplified by their being more responsible, ambitious, and self-disciplined. In addition, firstborns tend to be more conforming to authority and respectful of parents (Manaster et al., 1998). Firstborns also tend to have higher IQs than their younger siblings – a reduction of about one IQ point is observed, on average, with each increment in birth rank (Zajonc and Mullally, 1997; Kristensen and Bjerkedal, 2007).

These and other birth-order differences in personality and behavior can be usefully understood from a Darwinian perspective on family life (Sulloway, 1996, 2010). Because they share, on average, only half of their genes, siblings will tend to compete unless the benefits of cooperating are greater than twice the costs (Hamilton, 1964). In this Darwinian story about sibling competition, birth order does not exert a direct biological influence on personality. For example, there are no genes for being a firstborn or a laterborn. Instead, birth order is best seen as a proxy for various environmental influences, particularly disparities in age, physical size, power, and status within the family. These physical and mental differences lead siblings to pursue alternative strategies in their efforts to maximize parental investment (which includes emotional as well as physical resources). This perspective on how sibling order shapes personality accords with research in behavioral genetics, which finds that most environmental influences on personality are not shared by siblings and hence belong to the 'nonshared environment' (Plomin and Daniels, 1987). Conceptualized in these terms, the family is not primarily a shared environment but rather a series of microenvironments that differ according to age, sex, birth order, and other sources of individual differences.

Prior to the twentieth century, half of all children did not survive childhood. Even minor differences in parental favor would have increased an offspring's chances of getting out of childhood alive. Because eldest children have already survived the perilous early years of childhood, they are more likely than younger siblings to reach the age of reproduction and to pass on their parents' genes. Quite simply, a surviving eldest child was generally a better Darwinian than a younger child, which is why parents in most traditional societies tend to bias investment, consciously or unconsciously, toward older offspring. An exception to this generalization involves youngest children born toward the end of a woman's reproductive career. These children also tend to be favored, since they cannot be replaced (Salmon and Daly, 1998).

Because laterborns generally receive less parental investment than firstborns, they also exhibit higher mortality rates in many cultures (Hertwig et al., 2002). Given that the evolutionary costs of risk-taking are lower whenever the likelihood of survival is lower, laterborns are predicted to take greater risks than their older siblings. Risk-taking can be considered a generalized personality characteristic and hence should extend to many different types of behavior. One test of this hypothesis has involved a meta-analysis of 24 previous studies of risk-taking in athletics, which included 8340 participants (Sulloway and Zweigenhaft, 2010). After controlling important background factors such as sibship size and social class, laterborns were found to be 1.5 times more likely than firstborns to participate in dangerous sports such as rugby, football, and downhill skiing. Similarly, among 700 brothers who played major league baseball, younger brothers were 1.7 times more likely to attempt to steal bases than their older brothers, 1.4 times more likely to be caught stealing bases, and 1.4 times more likely to successfully complete stolen base attempts.

Even when parents do not favor one offspring over another, siblings compete to prevent favoritism. Siblings do so, in part, by cultivating family niches that correspond closely to differences in birth order. Firstborns, for example, tend to act as surrogate parents toward their younger siblings, which is a good way of currying parental favor. As a consequence, firstborns tend to be more conservative and parent identified than their younger siblings, which is one of the most robustly documented findings in the literature. Laterborns cannot compete as effectively as firstborns for this surrogate parent niche, since they cannot babysit themselves. Laterborns therefore seek alternative family niches that will help them to

cultivate parental favor in different ways. To do so, they must often look within themselves for latent talents that can only be discovered through systematic experimentation. Toward this end, laterborns tend to be more open to experience – that is, more imaginative, prone to fantasies, and unconventional – propensities that offer an increased prospect of finding a valued and unoccupied family niche.

In addition to their efforts to cultivate alternative family niches, siblings diverge in personality and interests because they employ differing strategies in dealing with one another. These strategies are similar to those observed in mammalian dominance hierarchies. Because firstborns are physically bigger than their younger siblings, they are more likely to employ physical aggression and intimidation in dealing with rivals. Firstborns are the 'alpha males' of their sibling group, and they generally boss and dominate their younger brothers and sisters. For their own part, laterborns tend to employ low-power strategies to obtain what they want, including pleading, whining, cajoling, humor, social intelligence, and, whenever expedient, appealing to parents for assistance.

Laterborns also tend to form coalitions with one another in an effort to circumvent the physical advantages enjoyed by the firstborn. Middle children are the most inclined to employ diplomatic and cooperative strategies. Some middle children are particularly adept at nonviolent methods of protest. Martin Luther King, Jr., the middle of three children, began his career as a champion of nonviolent reform by interceding in the episodes of merciless teasing that his younger brother inflicted upon their elder sister.

Only children represent a controlled experiment in birth-order research. They have no siblings and therefore experience no sibling rivalry. Consequently, they are not driven to occupy a particular family niche. Although only children, like other firstborns, are generally ambitious and conform to parental authority, they are intermediate between firstborns and laterborns on most other personality traits. Because age spacing can affect functional sibling order, a firstborn whose next younger sibling is six or more years younger is effectively like an only child. Similarly, large age gaps can make some laterborns into functional firstborns or only children.

That brothers and sisters differ from one another for strategic reasons, rather than randomly, has been shown by studies involving more than one sibling from the same family (Schachter, 1982). In one study, firstborns were found to be significantly different in personality and interests from secondborns, who were significantly different from thirdborns. By contrast, the first and third siblings were not as different as adjacent pairs, presumably because of less competition. This process of sibling differentiation has been termed 'deidentification' and extends to relationships with parents. For example, a firstborn child sometimes identifies more strongly with one parent than another. In such cases, the secondborn tends to identify more strongly with the parent that is not already preferred by the firstborn. This process of sibling differentiation is generally adaptive by reducing direct competition for scarce family resources, exemplifying what Darwin (1859) called the 'principle of divergence.'

The most compelling evidence for birth-order effects in personality comes from studies in which siblings assess each other's personalities (Paulhus et al., 1999; Healey and Ellis, 2007; Sulloway, 1999, 2010). Such within-family designs control for the kinds of spurious correlations that can result from comparing individuals from different family backgrounds. Studies based on such direct sibling comparisons exhibit consistent birth-order effects in the expected direction. When the results are organized according to the Five-Factor Model of personality (Costa and McCrae, 1992), firstborns tend to be more conscientious than laterborns, whereas laterborns tend to be more agreeable, extraverted, and open to experience than firstborns.

Although reasonably consistent patterns for birth order and personality are observed according to the Five-Factor Model of personality, findings are significantly heterogeneous for three of the five personality dimensions. For example, firstborns tend to be more assertive than laterborns, which is an indicator of extraversion, but laterborns tend to score higher on most other facets of extraversion, which include being more fun-loving, sociable, and excitement-seeking. Similarly, laterborns tend to be more open to experience in the sense of being unconventional, whereas firstborns tend to be more open to experience in the sense of being intellectually oriented. Finally, firstborns are more neurotic in the sense of being anxious about status, but laterborns are more neurotic in the sense of being self-conscious.

As measured by direct sibling comparisons within the family, birth-order differences explain about 4% of the variance in personality, less than does gender and substantially more than do age, family size, or social class. In studies controlled for differences in age, sex, social class, and sibship size, siblings are about twice as likely to exhibit traits that are consistent with their sibling positions as to exhibit inconsistent traits. In short, not every laterborn has a laterborn personality (just as some firstborns deviate from the expected trend), but a reasonably consonant pattern is nevertheless present.

One still-unresolved question about birth order and personality is the extent to which within-family patterns of behavior transfer to behavior outside the family of origin. Studies suggest that birth-order effects observed in extrafamilial contexts are about one-third to one-half the magnitude of those manifested within the family (Sulloway, 1999, 2001). Relative to firstborn spouses and roommates, for example, laterborn spouses and roommates are generally perceived to be more agreeable and extraverted, but less conscientious and neurotic. Outside the family of origin, birth-order effects seem to manifest themselves most strongly in intimate living relationships and in dominance hierarchies. These findings are not surprising, since they involve the kind of behavioral contexts in which sibling strategies were originally learned.

Behavior during Radical Revolutions

Some of the most consistent evidence for sibling differences in behavior outside the family of origin comes from social and intellectual history. During socially radical revolutions, laterborns have generally been more likely than firstborns to question the status quo and to adopt a revolutionary

alternative. This difference is observed even after controlling for the fact that laterborns, in past centuries at least, appear to have been more socially liberal than firstborns. As a rule, these effects are context sensitive. During the Protestant Reformation, for example, laterborns were more likely than firstborns to suffer martyrdom in support of the Reformed faith. By contrast, in countries that turned Protestant, such as England, firstborns were more likely than laterborns to suffer martyrdom for their refusal to abandon their allegiance to the Catholic faith. Thus laterborns gave their lives in the service of radical rebellion, whereas firstborns did so in an effort to preserve the waning orthodoxy. There was no generalized tendency, however, for laterborns to become 'martyrs' (Sulloway, 1996).

Similarly, during the French Revolution firstborn deputies to the National Convention generally voted according to the expectations of their social class, whereas laterborn deputies were more likely to vote in the opposite manner. For this reason, there was only a modest tendency for firstborns and laterborns to vote in a particular manner, since voting was generally influenced by other important considerations that determined what it meant to conform or rebel in a rapidly changing political environment.

In response to radical conceptual changes in science one finds similar differences by birth order (Sulloway, 1996, 2009). Firstborns tend to be the guardians of what Thomas Kuhn (1970) has called 'normal' science, during which research is guided by the prevailing paradigms of the day. By contrast, laterborns tend to be the outlaws of science, sometimes flaunting its accepted methods and assumptions in the process of attempting radical conceptual change. During the early years of the Copernican Revolution, which challenged church doctrine by claiming that the earth rotates around the sun, laterborns were five times more likely than firstborns to endorse this heretical theory. Copernicus himself was the youngest of four children. When Charles Darwin, the fifth of six children, became an evolutionist in the 1830s, he was 10 times more likely to do so than a firstborn. During other notable revolutions in science – including those led by laterborns such as Bacon, Descartes, Hutton, Semmelweis, and Heisenberg, and by occasional firstborns such as Newton and Einstein – younger siblings have typically been twice as likely as firstborns to endorse the new and radical viewpoint. Conversely, when new scientific doctrines, such as vitalism and eugenics, have appealed strongly to social conservatives, firstborns have been more likely than laterborns to pioneer and endorse such novel but ideologically conservative ideas. These birth-order effects typically fade over the course of scientific progress, as conceptual innovations accumulate supporting evidence and eventually convince the scientific majority.

In spite of their predilection for supporting radical innovations, laterborns have no monopoly on scientific truth. They were nine times more likely than firstborns to support Franz Joseph Gall's bogus theory of phrenology, which held that character and personality could be read by means of bumps on the head. In their willingness to question the status quo, laterborns run the risk of error through overeager rebellion, just as firstborns sometimes err by resisting valid conceptual changes until the mounting evidence can no longer be denied.

During 'normal' science, firstborns possess a slight advantage over laterborns. Being more academically successful, firstborns are more likely than laterborns to become scientists. They also tend to win more Nobel prizes. This finding might seem surprising, but, according to the terms of Nobel's will, Nobel prizes have generally been given for 'discoveries' or creative puzzle solving in science, not for radical conceptual revolutions. Firstborn scientists who have innovated within the system include James Watson and Francis Crick, who together unraveled the structure of DNA, and Jonas Salk, who developed the polio vaccine. Such historical facts highlight another important point, namely, that firstborns and laterborns do not differ in overall levels of 'creativity.' Rather, firstborns and laterborns are preadapted to solving dissimilar kinds of problems by employing disparate kinds of creative strategies.

Family Sentiments

The kinds of birth-order effects that are observed during radical historical revolutions may depend as much on differences in 'family sentiments' as they do on personality. As Salmon and Daly (1998) have shown, firstborns (and to a lesser extent lastborns) are more strongly attached to the family system than are middle children. Historically, radical revolutions have tapped differences in family sentiments in two important ways. First, being considerably older than their offspring, parents were more likely to endorse the status quo, given that age is one of the best predictors of the acceptance of new and radical ideas (Hull et al., 1978). For this reason, endorsing a radical revolution has usually meant opposing parental values and authority, something that firstborns (and to a lesser extent lastborns) are less likely to do than are middleborns. Second, most radical revolutions, even in fields such as science, have tended to raise issues that are directly relevant to issues of parental investment and discrimination among offspring, including filial loyalty and overall identification with the family system. During the Reformation, for example, Protestant leaders such as Martin Luther strongly advocated the right to marriage by previously celibate clergymen and nuns, who tended to be younger sons and daughters. These Protestant leaders also advocated the egalitarian principles of partible inheritance, by which property – and even political rule – were subdivided equally among offspring (Fichtner, 1989). During the height of the controversies raging over Darwin's theory of evolution, Darwin noted that discriminatory inheritance practices posed a serious impediment to human evolution, remarking to Alfred Russel Wallace: "But oh, what a scheme is primogeniture for destroying natural selection!" (Sulloway, 1996: p. 54).

Even when radical ideology does not play a significant role in conceptual change, and when discriminatory inheritance systems are also not a factor, differences in identification with the family can affect social and political attitudes. As Salmon (1998) has shown experimentally, political speeches appeal differentially to individuals by birth order depending on whether kinship terms are included in the speech. Firstborns and lastborns are more likely to react positively to speeches that employ kinship terms such as 'brother' and 'sister,' whereas

middle children prefer speeches that employ references to 'friends.' To the extent that radical social movements make use of kinship terms, which they often do, birth-order differences in family sentiments will tend to influence how siblings react to radical change.

Conclusion

In past centuries birth order and functional sibling order have influenced such diverse social and political phenomena as royal succession, expansionist military campaigns, religious wars and Crusades, geographic exploration, and inheritance laws. Even today, birth order and family niches more generally are among the environmental sources of personality because they cause siblings to experience the family environment in dissimilar ways. In particular, birth order introduces the need for differing strategies in dealing with sibling rivals as part of the universal quest for parental favor. This is a Darwinian story, albeit one with a marked environmental twist. Although siblings appear to be hard-wired to compete for parental favor, the specific niche in which they have grown up determines the particular strategies they adopt within their own family. Finally, because birth order and family niches underlie differences in family sentiments, including filial loyalty and self-conceptions about family identity, the family has historically supplied a powerful engine for revolutionary change.

Abstract

What would language be like if its transmission were not based on the vocal tract and the ear? How is language organized when it is based instead on the hands moving in space, and the eyes? Do these transmission channel differences result in any deeper differences? The existence of primary signed languages allow us to inquire about the determinants of language organization from a new perspective. Recent research into primary signed languages passed down from one generation of deaf people to the next has made clear that there are many different signed languages arising independently of one another, and of the spoken languages of their surrounding communities. At their core, spoken and signed languages are found to be essentially the same in terms of organizational principles and rule systems. Nevertheless, on the surface, signed and spoken languages differ markedly. American Sign Language and other signed languages display complex linguistic structure, but unlike spoken languages, convey much of their structure by manipulating spatial relations, making use of spatial contrasts at all linguistic levels. The surface and core properties of spoken and signed languages allow us to examine in depth the neurological basis for language and the human capacity for creating linguistic systems in a new way.

Until recently, most of the scientific understanding of the human capacity for language has come from the study of spoken languages. It has been assumed that the organizational properties of language are connected inseparably with the sounds of speech, and the fact that language is normally spoken and heard determines the basic principles of grammar, as well as the organization of the brain for language. There is good evidence that structures involved in breathing and chewing have evolved into a versatile and efficient system for the production of sounds in humans. Studies of brain organization indicate that the left cerebral hemisphere is specialized for processing linguistic information in the auditory–vocal mode and that the major language-mediating areas of the brain are connected intimately with the auditory–vocal channel. It has even been argued that hearing and the development of speech are necessary precursors to this cerebral specialization for language. Thus, the link between biology and linguistic behavior has been identified with the particular sensory modality in which language has developed.

Although the path of human evolution has been in conjunction with the thousands of spoken languages the world over, recent research into signed languages has revealed the existence of primary linguistic systems that have developed naturally independent of spoken languages in a visual–manual mode. American Sign Language (ASL), for example, a sign language passed down from one generation to the next of deaf people, has all the complexity of spoken languages, and is as capable of expressing science, poetry, wit, historical change, and infinite nuances of meaning as are spoken languages. Importantly, ASL and other signed languages are not derived from the spoken language of the surrounding community: rather, they are autonomous languages with their own grammatical form and meaning. Although it was thought originally that signed languages were universal pantomime, or broken forms of spoken language on the hands, or loose collections of vague gestures, now scientists around the world have found that there are signed languages that spring up wherever there are communities and generations of deaf people (Klima and Bellugi, 1988).

One can now specify the ways in which the formal properties of languages are shaped by their modalities of expression, sifting properties peculiar to a particular language mode from more general properties common to all languages. ASL, for example, exhibits formal structuring at the same levels as spoken languages (the internal structure of lexical units and the grammatical scaffolding underlying sentences) as well as the same kinds of organizational principles as spoken languages. Yet the form this grammatical structuring assumes in a visual–manual language is apparently deeply influenced by the modality in which the language is cast (Bellugi, 1980).

The existence of signed languages allows us to enquire about the determinants of language organization from a different perspective. What would language be like if its transmission were not based on the vocal tract and the ear? How is language organized when it is based instead on the hands moving in space and the eyes? Do these transmission channel differences result in any deeper differences? It is now clear that there are many different signed languages arising independently of one another and of spoken languages. At the core, spoken and signed languages are essentially the same in terms of organizational principles and rule systems. Nevertheless, on the surface, signed and spoken languages differ markedly. ASL and other signed languages display complex linguistic structure, but unlike spoken languages, convey much of their structure by manipulating spatial relations, making use of spatial contrasts at all linguistic levels (Bellugi et al., 1989).

The Structure of Sign Language

As already noted, the most striking surface difference between signed and spoken languages is the reliance on spatial contrasts, most evident in the grammar of the language. At the lexical level, signs can be separated from one another

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52018-2

Figure 1 Spatially organized (three-dimensional) morphology in ASL.

Figure 2 Spatialized syntax.

minimally by manual parameters (handshape, movement, location). The signs for *summer*, *ugly*, and *dry* are just the same in terms of handshape and movement, and differ only in the spatial location of the signs (forehead, nose, or chin). Instead of relying on linear order for grammatical morphology, as in English (*act, acting, acted, acts*), ASL grammatical processes nest sign stems in spatial patterns of considerable complexity (see Figure 1), marking grammatical functions such as number, aspect, and person spatially. Grammatically complex forms can be nested spatially, one inside the other, with different orderings producing different hierarchically organized meanings.

Similarly, the syntactic structure specifying relations of signs to one another in sentences of ASL is also essentially organized spatially. Nominal signs may be associated with abstract points in a plane of signing space, and it is the direction of movement of verb signs between such endpoints that marks grammatical relations. Whereas in English, the sentences 'the cat bites the dog' and 'the dog bites the cat' are differentiated by the order of the words, in ASL these differences are signaled by the movement of the verb between points associated with the signs for *cat* and *dog* in a plane of signing space. Pronominal signs directed toward such previously established points or loci clearly function to refer back to nominals, even with many signs intervening (see Figure 2). This spatial organization underlying syntax is a unique property of visual-gestural systems (Bellugi et al., 1989).

The Acquisition of Sign Language by Deaf Children of Deaf Parents

Findings revealing the special grammatical structuring of a language in a visual mode lead to questions about the acquisition of sign language, its effect on nonlanguage visuospatial cognition, and its representation in the brain. Despite the dramatic surface differences between spoken and signed languages – simultaneity and nesting sign stems in complex co-occurring spatial patterns – the acquisition of sign language by deaf children of deaf parents shows a remarkable similarity to that of hearing children learning a spoken language. Grammatical processes in ASL are acquired at the same rate and by the same processing by deaf children as are grammatical processes by hearing children learning English, as if there were a biological timetable underlying language acquisition.

First words and first signs appear at around 12 months; combining two words or two signs in children, whether deaf or hearing, occurs by about 18–20 months, and the rapid expansion signaling the development of grammar (morphology and syntax) develops in both spoken and signed languages by about 3–3.5 years. Just as hearing children show their mastery and discovery of grammatical regularities by producing overregularizations ('I goed there,' 'we helded the rabbit'), deaf children learning sign language show evidence of learning the spatial morphology signaling plural forms and aspectual forms

Figure 3 Deaf children's grammatical overregularizations.

by producing overregularizations in spatial patterns (see Figure 3).

Neural Systems Subserving Visuospatial Languages

The differences between signed and spoken languages provide an especially powerful tool for understanding the neural systems subserving language. Consider the following: In hearing/speaking individuals, language processing is mediated generally by the left cerebral hemisphere, whereas visuospatial processing is mediated by the right cerebral hemisphere. But what about a language that is communicated using spatial contrasts rather than temporal contrasts? On the one hand, the fact that sign language has the same kind of complex linguistic structure as spoken languages and the same expressivity might lead one to expect left hemisphere mediation. On the other hand, the spatial medium so central to the linguistic structure of sign language clearly suggests right hemisphere or bilateral mediation. In fact, the answer to this question is dependent on the answer to another, deeper, question concerning the *basis* of the left hemisphere specialization for language.

Specifically, is the left hemisphere specialized for language processing per se (i.e., is there a brain basis for language as an independent entity)? Or is the left hemisphere's dominance generalized to process any type of information that is presented in terms of temporal contrasts? If the left hemisphere is indeed specialized for processing language itself, sign language processing should be mediated by the left hemisphere, as is spoken language. If, however, the left hemisphere is specialized for processing fast temporal contrasts in general, one would expect sign language processing to be mediated by the right hemisphere. The study of sign languages in deaf signers permits us to pit the nature of the signal (auditory-temporal vs visual-spatial) against the type of information (linguistic vs nonlinguistic) that is encoded in that signal as a means of examining the neurobiological basis of language (Poizner et al., 1990).

One program of studies examines deaf lifelong signers with focal lesions to the left or the right cerebral hemisphere. Major areas, each focusing on a special property of the visual-gestural modality as it bears on the investigation of brain organization for language, are investigated. There are intensive studies of large groups of deaf signers with left or right hemisphere focal lesions in one program (Salk); all are highly skilled ASL signers, and all used sign as a primary form of communication throughout their lives. Individuals were examined with an extensive battery of experimental probes, including formal testing of ASL at all structural levels; spatial cognitive probes sensitive to right-hemisphere damage in hearing people; and new methods of brain imaging, including structural and functional magnetic resonance imaging (MRI, fMRI), event-related potentials (ERP), and positron emission tomography (PET). This large pool of well-studied and thoroughly characterized subjects, together with new methods of brain imaging and sensitive tests of signed as well as spoken language allows for a new perspective on the determinants of brain organization for language (Hickok and Bellugi, 2000; Hickok et al., 1996).

Left Hemisphere Lesions and Sign Language Grammar

The first major finding is that so far only deaf signers with damage to the left hemisphere show sign language aphasias. Marked impairment in sign language after left hemisphere lesions was found in the majority of the left hemisphere damaged (LHD) signers, but not in any of the right hemisphere damaged (RHD) signers, whose language profiles were much like matched controls. Figure 4 presents a comparison of LHD, RHD, and normal control profiles of sign characteristics from The Salk Sign Diagnostic Aphasia Examination – a measure of sign aphasia. The RHD signers showed no impairment at all in any aspect of ASL grammar; their signing was rich, complex, and without deficit, even in the spatial organization underlying sentences of ASL. By contrast, signers with LHD showed markedly contrasting profiles: one was agrammatic after her stroke, producing only nouns and a few verbs with none of the grammatical apparatus of ASL, another made frequent paraphasias at the sign internal level, and several showed many grammatical paraphasias, including neologisms, particularly in morphology.

Another deaf signer showed deficits in the spatially encoded grammatical operations which link signs in sentences, a remarkable failure in the spatially organized syntax of the language. Still another deaf signer with focal lesions to the left hemisphere reveal dissociations not found in spoken language: a dissociation between sign and gesture, with a cleavage between capacities for sign language (severely impaired) and manual pantomime (spared). In contrast, none of the RHD signers showed any within-sentence deficits; they were completely unimpaired in sign sentences and not one showed aphasia for sign language (in contrast to their marked nonlanguage spatial deficits, described below) (Hickok and Bellugi, 2000; Hickok et al., 1998).

Figure 4 Left hemisphere lesions lead to sign language aphasias.

Figure 5 Rhyming task with LHD and RHD signers.

Moreover, there are dramatic differences in performance between LHD and RHD signers in formal experimental probes of sign competence. For example, a test of the equivalent of rhyming in ASL provides a probe of phonological processing. Two signs 'rhyme' if they are similar in all but one phonological parametric value such as handshape, location, or movement. To tap this aspect of phonological processing, subjects are presented with an array of pictured objects and asked to pick out the two objects whose signs rhyme (Figure 5). The ASL signs for *key* and *apple* share the same handshape and movement, and differ only in location, and thus are like rhymed pairs. LHD signers are significantly impaired relative to RHD signers and controls on this test, another sign of the marked difference in effects of right- and left-hemisphere lesions on signing. On other tests of ASL processing at different structural levels, there are similar distinctions between left- and right-lesioned signers, with the right-lesioned signers much like the controls, but the signers with left hemisphere lesions significantly impaired in language processing. Moreover, studies have found that there can be differential breakdown of linguistic components of sign language (lexicon and grammar) with different left hemisphere lesions.

Right Hemisphere Lesions and Nonlanguage Spatial Processing

These results from language testing contrast sharply with results on tests of nonlanguage spatial cognition. RHD signers are significantly more impaired on a wide range of spatial cognitive tasks than LHD signers, who show little impairment. Drawings of many of the RHD signers (but not those with LHD) show severe spatial distortions, neglect of the left side of space, and lack of perspective. RHD deaf signers show lack of perspective, left neglect, and spatial disorganization on an array of spatial cognitive nonlanguage tests (block design, drawing, hierarchical processing), compared with LHD deaf signers. Yet, astonishingly, these severe spatial deficits among RHD signers do not affect their competence in a spatially nested language, ASL. The case of a signer with a right parietal lesion leading to severe left neglect is of special interest: Whereas his drawings show characteristic omissions on the left side of space, his signing (including the spatially organized syntax) is impeccable, with signs and spatially organized syntax perfectly maintained.

The finding that sign aphasia follows left hemisphere lesions but not right hemisphere lesions provides a strong case for a modality-independent *linguistic* basis for the left hemisphere specialization for language. These data suggest that the left hemisphere is predisposed biologically for language, independent of language modality. Thus, hearing and speech are not necessary for the development of hemisphere specialization – sound is not crucial. Furthermore, the finding of a dissociation between competence in a spatial language and competence in nonlinguistic spatial cognition demonstrates that it is the type of information that is encoded in a signal (i.e., linguistic vs spatial information) rather than the nature of the signal itself (i.e., spatial vs temporal) that determines the organization of the brain for higher cognitive functions.

Language, Modality, and the Brain

Analysis of patterns of breakdown in deaf signers provides new perspectives on the determinants of hemispheric specialization for language. First, the data show that hearing and speech are not necessary for the development of hemispheric specialization: sound is *not* crucial. Second, it is the left hemisphere that is dominant for sign language. Deaf signers with damage to the left hemisphere show marked sign language deficits but relatively intact capacity for processing nonlanguage visuospatial relations. Signers with damage to the right hemisphere show the reverse pattern. Thus, not only is there left hemisphere specialization for language functioning, there is also complementary specialization for nonlanguage spatial functioning. The fact that grammatical information in sign language is conveyed via spatial manipulation does not alter this complementary specialization.

Furthermore, components of sign language (lexicon and grammar) can be selectively impaired, reflecting differential breakdown of sign language along linguistically relevant lines. These data suggest that the left hemisphere in humans may have an innate predisposition for language, regardless of the modality. Since sign language involves an interplay between visuospatial and linguistic relations, studies of sign language breakdown in deaf signers may, in the long run, bring us closer to the fundamental principles underlying hemispheric specialization.

Abstract

Deaf and hearing persons who routinely use a signed language to communicate are subject to many of the same communication impairments that befall hearing users of spoken language. However, the expression of sign language impairment is poorly understood. Here we examine the effects of aphasia, apraxia, and Parkinson's disease on sign language use. We observe that the effects of these disorders are largely homologous to those found in spoken languages. We then consider childhood developmental disorders, and focus on autism spectrum disorder and stuttering. We discuss how the well-known communicative impairments associated with severe autism is expressed in signers with autism. We discuss how errors in copying limb movements seen in children with autism, is realized in sign language. Finally we turn to a discussion of stuttering, a common trait in speech development, which we claim is largely absent in sign language. Taken together the examination of language disorders in users of signed and spoken languages provides a powerful means to understand the common neural substrates of human communication while leaving in stark relief those properties of human communication that are specific to its modality of expression.

Signed languages of the deaf are naturally evolving linguistic systems exhibiting the full range of linguistic complexity found in spoken languages. Contrary to popular belief sign language is not universal. Just as there are a multitude spoken language communities around the world (e.g., speakers of Quechua, Farsi, Portuguese, and English), there are many different sign language communities (e.g., signers of Langue des Signes du Québec, Deutsche Gebärdensprache (DGS), Taiwan Ziran Shouyu, and British Sign Language (BSL), to name but a few). Signed languages are not invented hand symbols that simply represent the words of a spoken language, nor are they elaborate and codified systems of pantomime. They are complete, natural languages in their own right, with forms and grammatical rules that are abstract, linguistically complex, and largely independent of their surrounding spoken language communities. Although individual signed languages often correspond to the same geographical and political regions that separate users of spoken languages (e.g., both German spoken language and DGS are found in Germany, while English and BSL are found in England), sign languages are autonomous of the spoken languages used within these regions (for example, American Sign Language (ASL) is also used in Nigeria and in the Philippines). Deaf communities utilize sign languages just as hearing communities use spoken languages. They are fully complementary forms of human communication. Many signed languages do have auxiliary systems for borrowing elements of spoken languages into a manual form. The most familiar of these are fingerspelling systems in which the hand or hands represent the alphabet (or written character) on the hands.

Deaf individuals are subject to the same disorders that affect language abilities in hearing persons, including developmental language disorders such as autism as well as acquired disorders, such as aphasia. However, given the fact that the transmission and reception modalities of speech and sign languages clearly differ, there is the theoretical possibility that one may observe modality-specific language impairments that only manifest in speech or sign. In this article we provide an introduction to some disorders that are common to both signed and spoken languages. Here we focus on adult neurological disorders, primarily aphasia, apraxia, and Parkinson's disease. We discuss the realization of these sign language disorders in relation to their spoken language counterparts. We then turn to the emerging field of developmental language disorders and briefly explore the impact of autism spectrum disorder (ASD) on signing abilities and finally consider whether there is an analogue to stuttering in a signed language. Much of the research on disordered signing has focused on deaf communities in the United States, hence the majority of the examples are drawn from ASL, but these are suggested to be representative of users of other signed languages. However, as worldwide research on signed languages continues to grow, we look forward to the confirmation of this premise and will be interested to learn about how different properties of signed languages may result in variations of impairment.

The consideration of linguistic impairments in signers provides a unique avenue for understanding whether symptoms associated with a language disorder reflect the unique demands of a language's mode of expression or reflects core linguistic and cognitive properties associated with human languages processing regardless of the modality of expression.

Sign Language Aphasia and Limb Apraxia

Damage to left-hemisphere cortical regions can result in acquired language impairments known as aphasia. Aphasia may differentially affect a patient's ability to produce, repeat, and/or comprehend language. Clinically, the constellation of symptoms associated with aphasia gives rise to distinct subtypes of aphasia. Brain damage may also result in impairment to the oral articulators that impede the ability to speak or sequence speech movements; this motor-based language impairment is termed an apraxia of speech. Theoretically, language deficits which impair the core representational properties of language (i.e., the aphasias) may be separated from purely implementation-based apraxias, in practice, it is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54043-4

often difficult to differentiate these impairments, as lesions are rarely discrete and patients often present with admixtures of symptoms.

Lesions to the left inferior frontal region are often associated with Broca's aphasia whereby a patient may have a severe problem in language production, with less pronounced impairments in language comprehension. Lesions in the posterior superior and middle temporal lobes regions often result in Wernicke's aphasia, which is marked by severe language comprehension problems with fluent, but often mistake-prone (i.e., paraphasic) speech output.

Deaf signers, like hearing speakers, also exhibit language disturbances when left-hemisphere cortical regions are damaged (for a review see Corina, 1998). Case histories coupled with more recent neuroimaging studies of healthy deaf subjects have provided confirming evidence for the importance of the left hemisphere in the mediation of signed languages (MacSweeney et al., 2008). Moreover there is good evidence that within the left hemisphere, cerebral organization in deaf signers follows an anterior/posterior dichotomy for language production and comprehension, respectively, which is familiar from speech. Emerging studies do suggest that sign languages may recruit the inferior and superior parietal lobe regions to a greater extent than is seen in spoken languages. These regions are involved in the guidance of manual and visuomotor behaviors as well as in the encoding of spatial environmental properties which may be used in the service of grammatical distinctions in signed languages such as ASL.

Sign Language Production

In spoken language aphasia, chronic language production impairments are typically associated with left-hemisphere frontal anterior lesions that involve the cortical zone encompassing the lower posterior portion of the left frontal lobe (e.g., Broca's area) and associated white-matter tracts (Goodglass, 1993) and the anterior insula (Dronkers et al., 2000). A classic case study reported in Poizner et al. (1987) provides clues to the role of left-hemisphere prefrontal regions in the mediation of signing. Patient G.D., a deaf signer with a large lesion in a left anterior frontal region encompassing Brodmann's area (BA) 44/45, presented with nonfluent signing with intact sign comprehension. Specifically, G.D.'s signing was effortful and dysfluent, with output often reduced to single-sign utterances. The signs she was able to produce were agrammatic, devoid of the movement modulations that signal morphosyntactic contrasts in fluent signing. As with hearing Broca's aphasics, this signer's comprehension of other's language was undisturbed by her lesion. Both at the single sign and sentence level, her comprehension were on par with that of control subjects.

Sign Language Comprehension

The fluent aphasias are typically manifested as severely impaired comprehension coupled with fluent, but often paraphasic (e.g., semantic and phonemic paraphasic) output. These aphasias are typically associated with lesions to left-hemisphere posterior temporal regions. Wernicke's aphasia, for example, is often associated with damage to the posterior regions of the left superior temporal gyrus. More recent work has suggested the contribution of the posterior middle temporal gyrus in cases of chronic Wernicke's aphasia (Dronkers et al., 2000).

Signers with left-hemisphere posterior lesions also evidence fluent sign aphasia. Two example cases are reported in Poizner et al. (1987) and Corina et al. (1992). These patients presented with severe sign comprehension difficulties in the face of relatively fluent but paraphasic sign output. While damage to left temporal cortex has been demonstrated to impair sign comprehension in some patients (Hickok et al., 2002), the lesions in these two patients did not occur in cortical Wernicke's area proper, but rather involved frontal lobe and inferior parietal areas. In both cases, lesions extended posteriorly to the supramarginal gyrus (SMG). This is interesting, as lesions associated with the SMG alone in users of spoken language do not typically result in severe speech comprehension deficits. These two cases suggest that sign language comprehension may be more dependent than speech on left-hemisphere inferior parietal areas, a difference that may reflect within-hemisphere reorganization for cortical areas involved in sign comprehension.

Sign Paraphasias

Language breakdown following left-hemisphere damage is not haphazard, but systematic and affects independently motivated linguistic categories. An example of the systematic patterning in sign and spoken language breakdown is illustrated by paraphasic errors (Corina, 2000). Paraphasia describes the erroneous substitution of an unexpected word for an intended target. Most semantic paraphasias represent the same part of speech as the target and have a clear semantic relationship to it, for example saying *hand* instead of *foot*. In contrast, phonemic or 'literal' paraphasias refer to the production of unintended sounds or syllables in the utterance of a partially recognizable word (Goodglass, 1993). Phonemic sound substitution in speech may result in another real word, related in sound but not in meaning (e.g., *telephone* becomes *television*). Also attested are cases in which the erroneous word shares both sound characteristics and meaning with the target (*broom* becomes *brush*; Goodglass, 1993).

Examples of ASL semantic paraphasias are well documented (Poizner et al., 1987). For example, subject P.D. produced clear lexical substitutions: BED for CHAIR, DAUGHTER for SON, QUIT for DEPART, etc. In general, the semantic errors of P.D. overlap in meaning and lexical class with the intended targets. Concerning phonemic errors, a priori we may expect to find an equal distribution of phonological errors affecting the four major formational parameters of ASL phonology: handshape, movement, location, and orientation. However, handshape configuration errors are the most widely reported, while paraphasias affecting movement, location, and orientation are infrequent (Corina, 2000). This is noteworthy as handshape is considered a separate autosegmental tier in formal treatment of ASL phonology (Sandler and Lillo-Martin, 2006).

An unusual case of sign paraphasia is reported by Hickok et al. (1996). A life-long signer, R.S., suffered an infarct to the left frontal operculum. Neurological examination revealed an initial expressive aphasia that largely resolved with lingering problems of word-finding and frequent phonemic paraphasia.

In the absence of limb apraxia, R.S. exhibited paraphasia restricted to two-handed signs. For example, for signs that require two hands to assume different handshapes and/or to move independently, R.S. would incorrectly fail to move one of her hands. In other cases, for signs where the appropriate movement of one hand was moved relative to the position of the other, R.S. would produce incorrect relational movements. That is, while the path movement itself was correct, it was not carried out correctly with respect to the spatial relationship of the other hand. In addition, during one-handed signing, she exhibited mirroring of movements and handshapes of the dominant hand on the nondominant hand that was somewhat reduced in degree of movement. This mirroring was not seen during nonlinguistic movement and was qualitatively different from mirror movements effecting distal movement sometimes seen in cases of hemiparesis (Hickok et al., 1996). These paraphasias do not have a clear analogy to errors seen in spoken language. These selective two-handed errors may be taken as an indication that the modality and/or form of a linguistic system may place unique demands on the neural mediation and implementation of a language. These errors can be taken as evidence for language-form specific linguistic impairment.

Induced Paraphasias

Additional insights into the neural control of paraphasic errors have been reported by Corina et al. (1999), who investigated sign language production in a deaf individual undergoing an awake left-hemisphere cortical stimulation mapping procedure for the surgical treatment of epilepsy. During the language-mapping portion of the procedure, the participant was required to sign (with his left hand) the names of line drawn pictures. Disruption of the ability to perform the task during stimulation was taken as evidence that the cortical region in question was integral to the language task (Stemmer and Whitaker, 1998).

Stimulation to two anatomical sites led to consistent naming disruption. One of these, an isolated frontal opercular site, corresponded to the posterior aspect of Broca's area, BA 44. A second site, located in the parietal opercular region, corresponded to the SMG, BA 40. Importantly, the nature of these errors was qualitatively different. Stimulation of Broca's area resulted in errors involving the motor execution of signs. These errors were characterized by a laxed articulation of the intended sign, with nonspecific movements (repeated tapping or rubbing) and a reduction in handshape configurations to a laxed-closed fist handshape. With stimulation of the SMG, S.T. produced both formational and semantic errors. Formational errors were characterized by repeated attempts to articulate the intended targets. Successive formational (i.e., phonological) approximations of the correct sign were common. The semantic errors were characterized as semantic substitutions that are formationally quite similar to the intended targets. One conceptualization of these data is that stimulation to Broca's area has a global effect on the motor output of signing, whereas stimulation to a parietal opercular site, the SMG, disrupts the correct selection of the linguistic components (including both phonological and semantic elements) required for sign naming.

Apraxia and Signed Language

Signed languages provide an important contrast to naturally occurring gestures and limb actions. Unlike naturalistic movements, linguistic motor behaviors are highly symbolic, hierarchically compositional, and conventionalized. The production of signs nevertheless requires that linguistic forms stored in memory be planned and executed, respectively, by the same somatotopic brain regions and manual articulators that mediate physically comparable nonlinguistic gestures. Thus, in principle one might expect that deficits in sign language use may be distinguished clinically from apraxic disturbances of learned movement execution (Geschwind and Damasio, 1985) as well as cases where gesture use and sign language use are uniformly impaired.

Apraxia is defined as an impairment of the execution of a learned movement in response to a stimulus that would normally elicit the movement. Such impairments are subject to the conditions that the afferent and efferent systems involved are intact, and that the difficulty is not due to inattentiveness or lack of cooperation (Geschwind and Damasio, 1985). The left inferior parietal lobe has been considered an area responsible for the representation of learned movement. Lesions associated with the left inferior parietal lobe result in an inability to perform and comprehend gestures, whereas damage more anterior to this region may result in production impairment with sparing of pantomime comprehension (Heilman et al., 1982; Rothi et al., 1991). Apraxic disorders may affect symbolic intransitive movements (such as saluting) as well as everyday movements (like dressing oneself), and may even impede the ability to copy meaningless limb movements. Most researchers acknowledge two main categories of apraxia: ideational apraxia and ideomotor apraxia. In ideational apraxia, the patient is specifically impaired in the ability to recall previously well-established actions, such as those involved in object use. Ideomotor apraxia refers to an inability to imitate an unfamiliar action or series of actions (McCarthy and Warrington, 1990).

Dissociations between sign impairments and ideational apraxias (disturbances in conventionalized gestures and object-oriented pantomimes) are evident. Patient W.L., for example, produced and comprehended pantomime normally but demonstrated marked deficits in sign language production and comprehension (Corina et al., 1992). His gestures were clearly intended to convey symbolic information that he ordinarily would have imparted with sign language. The case of W.L. emphasizes that sign language impairments following left-hemisphere damage are not simply attributable to undifferentiated impairments in the motoric instantiation of symbolic representations, but in fact reflect disruptions to a manually expressed linguistic system. This conclusion has recently been supported by Marshall et al. (2004), who report on the dissociation of sign and gesture in Charles, an aphasic user of BSL. Once again, the ability to use nonlinguistic gesture was intact, while sign language expression showed significant impairment.

In contrast, aphasic subject G.D., who had a large frontoanterior lesion and was dysfluent in sign production, showed impaired ability to produce representational intransitive and transitive movements to command, but nevertheless showed

normal performance on a pantomime recognition test (Poizner et al., 1987). Subject Maureen reported by Marshall et al. (2005), a bilingual user of BSL with a left-hemisphere infarct in the vicinity of the middle cerebral artery exhibited a dense limb apraxia, that like G.D. affected, her signing and the reproduction of both meaningful and meaningless limb movements. She was unable to gesture the use of common objects that she nevertheless used in spontaneous everyday activities.

The sparing of pantomime comprehension in the face of aphasic comprehension impairments emphasizes the fact that language impairments following left-hemisphere damage are not attributable to undifferentiated symbolic impairments. However the fact that limb apraxia can co-occur with sign language production deficits as in the cases of G.D. and Maureen, also remind us of the close coupling between skilled movement abilities and execution of sign language. This point in reinforced by the fact that we have yet to witness a signer who shows spared execution of skilled nonlinguistic movement with a clear impairment in the production of sign language.

Parkinson's Disease

Parkinson's disease is a degenerative disorder of the brain that affects the extrapyramidal motor system and is mainly characterized by progressive tremor, bradykinesia (slowness of movement), and rigidity. Degeneration of the substantia nigra with subsequent decrease of striatal dopamine is responsible for the motor and cognitive disturbances seen in Parkinson's patients (Litvan, 1996). The motor deficits observed in these subjects are not specific to language but are evidenced across the general domain of motor behaviors. In hearing patients with Parkinson's disease, motor system dysfunction affects the speech articulators. The initial problem in the untreated patient is a failure to control respiration for the purpose of speech, and there follows a forward progression of articulatory symptoms involving the larynx, pharynx, tongue, and, finally, the lips (Critchley, 1981). Perceptual features of speech changes include aprosody (i.e., monopitch, monoloudness, diminished stress contrasts, and rate abnormalities), impairment of articulation (such as imprecise consonants), and vocal quality deviations (such as harsh or breathy voice). Physiological studies show that patients with Parkinson's disease have reduced articulatory displacements relative to normal speakers, which may appear as rigidity, and improper coordination of agonist–antagonist muscle pairs or groups (Gentil et al., 1995).

Studies of deaf persons with Parkinson's disease highlight the importance of the extrapyramidal motor system and basal ganglia in the mediation of sign language. The sign language deficits observed in Parkinsonisan signing are an expression of the generalized motor impairments common in Parkinson's disease. Poizner and colleagues have presented several case studies of Parkinsonian signers (Brentari et al., 1995). These signers show disturbed joint use, flattening of phonological distinctions, and timing disruption. Signers with Parkinson's disease have been described as signing in a monotonous fashion, with a severely restricted range of temporal rates and tension in signing, two features which normally serve to signal emphasis. Accompanying restrictions in limb movements are deficits in the motility of facial musculature, which further reduce expressivity in signing.

In Parkinsonian signing the scope of sign movement and precision of articulation are compromised. These changes include the distalization of movements, reductions in contact between sign articulators, and laxing of handshapes. Distalization of movement refers to the displacement of sign movements to joints closer to the extremities. For example, a sign like GIVE contains a path movement away from the signer and is normally articulated by straightening the elbow joint, thus moving the hand away from the body. A distalization of this movement would maintain the joint angle of the elbow and substitute an outward nod of the wrist, also moving the hand away from the signer. The end result is maintained directionality of movement with reduced articulatory demands. However, when this displacement occurs the perceptual saliency of signing suffers.

In Parkinsonian signing, there is often a systematic reduction of sign articulation that results in signs being articulated at the torso (as opposed to distinct, lexically specified locations). For example, Brentari and Poizner (1994) report their subject J.H. as signing BOY, normally articulated on the forehead, at the torso level. In fact, most of J.H.'s signs were articulated near the waist during free conversation. In Parkinsonian signers, physical contacts between the major articulators and body locations may be entirely lost. The lack of contact is consistent with a description of overall smoothing of articulation in signers with Parkinson's disease; maintenance of physical contacts with body locations probably places significant demands on the updating and programming of movement plans used in signing. The handshapes of signers with Parkinson's disease are often quite lax and do not maintain the crisp closure or opening of finger postures seen in normal signing. Importantly, the handshapes observed (and indeed all the articulatory distinctions) are approximations of the intended form, and not incorrect substitutions. Differences in hand orientation have been shown to migrate toward less-marked orientations about the sagittal plane, and reductions in the magnitude of orientation changes required by some signs have been documented (Brentari and Poizner, 1994). These findings are consistent with a general disruption of motor control that leads to phonetic disruptions in signing. This can be contrasted to the phonemic disruption apparent in aphasic signing.

All Parkinsonian patients typically show hesitation and slowing in the initiation and execution of movements. Sequential movements appear to be particularly difficult. Indeed, slowness in movement execution and slowness in switching are common manifestations of basal ganglia disease (Agostino et al., 1992). Signers with Parkinson's disease tend to execute all signs in a slow and uniform temporal rate. Parkinsonian subjects show similar temporal pauses between words and phrases (unlike normal signing); this lack of temporal differentiation adds to the perceptual phenomena of monotonous signing. The lack of differentiation may very well reflect disruption of processes involved in the rapid motor shifts that are required for fluent multiword signing.

In summary, the general movement disorders associated with Parkinson's disease affect sign language abilities and result in phonetic disruption in the articulation of signing. Motor

disruption leads to errors involving timing, scope, and precision of articulation features which are common to both Parkinsonian speech and signing. The study of timing relationships in signing provides further evidence that basal ganglia dysfunction affects not only movement execution (e.g., slowing) but also the switching between movements. Taken together, these studies illustrate the benefits of addressing questions of motor control from a perspective of sign language production.

Developmental Disorders of Sign Language

Studies of developmental disorders that affect sign language use are regrettably rare. The lack of systematic studies is hampered by several factors including the lack of reliable and normative developmental measures for sign language production and comprehension. In addition, the great heterogeneity in language exposure, levels of hearing loss, and educational placement (mainstreamed vs residential school, oral-based vs sign-based curriculums, etc.), coupled with the fact that deafness is often a comorbid symptom of a wide range of developmental disorders, makes systematic studies of subsets of already low-incidence populations difficult. However, some headway is being made (see for example, Mason et al., 2010; Quinto-Pozos et al., 2011).

In considering developmental disorders, one can ask, how do developmental disorders which impact spoken language abilities manifest in a deaf user of a signed language? One can also ask, whether there are, as of yet, unidentified language disorders that are specific to signed languages that do not have a clear analogy to impairments seen in users of spoken languages. Equally interesting is whether there are impairments in spoken languages that do not have clear analogue in signed language.

Autism

ASD consists of a set of neurobiological developmental disorders characterized by communicative and social deficits as well as repetitive, stereotyped behaviors (Centers for Disease Control, 2012a). ASD appears to be more frequent in the deaf population than in the general population (Szymanski et al., 2012; Jure et al., 1991) and there is evidence that severe hearing loss occurs in the ASD population at a rate of about 10 times than that of the general population (Rosenhall et al., 1999).

Clinicians have had interest in the use of visual manual communication as adjunctive therapy for nonverbal hearing children with autism. Early studies suggested that even fairly brief simultaneous communication or sign language training can be an effective means of improving communication skills in low-functioning hearing autistic children. Studies suggest that these children can often learn a small set of sign language vocabulary, with some showing progression to two-sign utterances. However, after the initial success of these early sign combinations, most hearing autistic children make only limited progress in terms of the average length and complexity of their sign utterances (Bonvillian et al., 1981).

Sign researchers have begun to explore the communicative patterns observed in the language of deaf children with autism. Poizner et al. (1987) briefly presents the case of Judith M, a severely autistic deaf signer. Judith M lived in a household with two deaf signing parents and two older deaf brothers, all highly fluent signers. As such the communicative impairments observed Judith M. cannot be attributed to an impoverished language exposure as may occur in cases of deaf (and autistic) signers raised in nonsigning homes. Judith M. began to exhibit autistic symptoms at age 11 months; this included a failure to make eye contact with persons around her and an abnormal interest in inanimate objects over social contacts. She exhibited language problems including a late onset of language use. She began to sign at age 5; however her language output was seldom spontaneous, and her language exhibited echolalia, where she repeated single signs from ASL sentences directed toward her. Her signing was reported as 'stiff' and her sign output was devoid of grammatical complexity seen in normal childhood signed utterances. Her echolalic signing was interspersed with meaningless repetitive movements that appear empty of communicative intent. She rarely made eye contact and tended to avoid social interaction other than to serve her own basic wants and needs. She showed no variation in facial expression or gesturing, nor did she attempt to mime or to communicate in other ways. Family members noted that she appeared generally incapable of abstract thought, and showed no indication that she responded to the feelings of others. Thus despite being immersed in a home environment in which sign communication rather than speech communication is the norm, Judith M. nevertheless presents with a profile of a severely autistic child with characteristic social and communicative impairments.

In a recent report, Shield and Meier (2012) reported a sample of five deaf children with ASD who exhibited a preponderance of sign language errors affecting the formational components of a sign. As noted previously, formational errors of sign production may independently affect the handshape, orientation, movement, and location of a sign. Shield and Meier (2012) reported that ASD children showed a robust tendency to fingerspell with a reversed palm orientation. Since fingerspelling is typically directed outward, such reversals suggest while learning to fingerspell, children with ASD reproduce handshapes as they appear from their own perspective, failing to reorient their own palm so that it faces their addressee. This marked pattern of sign articulation has been reported in the imitation of body movements by hearing children with ASD. A compelling finding from a number of studies is that hearing children with ASD tend to reverse the direction of observed palm orientations when imitating the gestures of others (Williams et al., 2004). These reversed palm orientations suggest that children with ASD imitate gestures as they appear from their own perspective. This has been taken as evidence for autism-specific deficit in self–other mapping, that is, a deficit in the process(es) by which children and adults observe the movements of others and map them onto their own bodies (Rogers and Pennington, 1991).

The studies of sign language in hearing children with ASD indicate that while signs may provide an alternative and at times a beneficial avenue for communication, the mere availability of this manual mode of communication does not fundamentally unlock the pervasive social and language impairments associated with ASD. The rare studies of deaf

signers with ASD provide a fascinating example of how complex manual movements, such as those used during fingerspelling, reflect a pervasive deficit in self-expression.

Stuttering

Stuttering is a disorder in which sounds, syllables, or words are repeated or prolonged, disrupting the normal flow of speech. Speech disruptions may be accompanied by struggling behaviors, such as rapid eye blinks or tremors of the lips. Stuttering affects people of all ages. Developmental stuttering is observed in approximately 5% of children between the ages of 2 and 5 as they are developing language skills. Boys are twice as likely to stutter as girls; as they get older, however, the number of boys who continue to stutter is three to four times larger than the number of girls. Most children outgrow stuttering. About 1% or less of adults stutter (NIDCD, 2012b). Stuttering may also be observed after acute brain damage, and recent studies have identified genes associated with familial developmental stuttering (Kang et al., 2010). However, the causal mechanisms remain poorly understood.

Studies of developmental stuttering have suggested that the left perisylvian region is anatomically more heterogeneous in people who stutter than in controls (Foundas et al., 2001), with recent studies showing reductions in white-matter tracts innervating left sensorimotor cortex (Buchel et al., 2004; Sommer et al., 2002). In contrast, with developmental stuttering, acquired stuttering is more often associated with subcortical lesions, in particular in the basal ganglia, than with lesions in cortical speech and motor regions (Giraud et al., 2008; Carluer et al., 2000).

The prevalence of stuttering in spoken languages has led sign language researchers to inquire whether such impairment is evidenced in naturally occurring signed languages. There are no detailed case study reports of stuttering solely in the manual modality. A drawback in these studies is the lack of an operational definition 'sign stuttering' (see Whitebread (2004) for a proposed hypothetical description of features of sign stuttering based largely on analogy with spoken language stuttering).

Two survey studies polled teachers for the deaf and other professionals knowledgeable about the deaf community and sign language whether they had observed 'sign stuttering' (Silverman and Silverman, 1971). Both of these studies had respondents who stated they had observed various dysfluencies in manual communication, and based on these polls the authors have concluded such disorders exist.

However, there are several reasons why one should be cautious about such claims as both of these studies have serious limitations. For example, in these second-hand reports, it is not clear if the teachers are reporting on individuals who are communicating in a signed language or a mixture of speech and sign. In addition, in the study by Cosyns et al. (2009) in the report of signers with 'stuttering-like dysfluencies ' the youngest reported afflicted individual is 10 years old, which is at odds with the developmental expression of this disorder commonly seen in users of spoken language.

While both Silverman and Silverman (1971) and Cosyns et al. (2009) conclude that stuttering exists in sign language, there are numerous reasons to argue otherwise. First, the lack of available evidence itself is noteworthy. While developmental speech stuttering affects 5% of the populations (NIDCD), despite years of informed studies of sign language acquisition in native deaf children, there seem to be few, if any, credible reports of such a common and pronounced stage of developmental stuttering behaviors in deaf signing children.

While there are some reports that children who stutter may have impaired manual skills, these are most often observed in concert with speech tasks, with increased speech stuttering leading to increased dysfluencies in manual motor behaviors (Saltuklaroglu et al., 2009). This suggests that the manual impairments seen in stutterers are a secondary consequence of the speech dysfluencies. It is of further interest to note that cases of musicians who have experienced stuttering-like behaviors tend to be associated with wind instruments where there is necessity of coordination between phonatory, oral, and manual behaviors.

This is not to say dysfluent signing does not occur, indeed as noted, manifestations of dysfluent sign production have been reported in aphasia, Parkinson's disease, and autism. However to characterize such dysfluency in terms of evidence for stuttering seems premature. The fact that there is such a low prevalence for developmental stuttering in sign language is perhaps overall more informative than trying to assume a homology between all speech and sign disorders. Taken at face value, developmental stuttering is communication disorder that might be specific to speech and is not manifested in a signed language.

Sign Language-Specific Deficits

Sign language researchers have begun to explore the presence of specific sign language disorders in deaf children (Mason et al., 2010; Morgan et al., 2007; Quinto-Pozos et al., 2011). These initial efforts make use of survey and case study approaches to examine a small number of deaf children, who despite having deaf signing parents, have been identified by teachers as having atypical problems in signing. In this way researchers are confident that the deficits are not confounded by variations in language acquisition that may be evident in deaf children who are raised in home where the parents do not know sign language. The goal of these studies is to document the presence of such disorders and to determine whether the deficits observed reflect general cognitive and/or global language impairments (and thus affect both spoken and signed language) or whether the impairments are in fact unique to the sign linguistic system.

In one example, Morgan et al. (2007) reported the case of Paul, a 5-year-old native deaf signer of BSL with a sign language impairment which they entertain as a possible analogue of specific language impairment (SLI) evidenced in a sign language. SLI is diagnosed where a deficit in normal spoken language acquisition is found with no apparent cognitive, social, or neurological cause (Leonard, 1998). Children with SLI typically have difficulty with the acquisition of phonology and morphosyntax.

Pauls' expressive BSL was restricted to short sentences made up of one or two signs with very limited grammar. He mostly produced a series of single signs with few grammatical inflections and few polymorphemic signs. He often used pointing to pictures, himself and others to avoid proper sentence structure.

He tended to use affective facial expression rather than using the face in coordination with the hands to mark questions. His receptive abilities mirrored his expressive profile, whereby he showed normal receptive vocabulary abilities for simple signs, but showed significant impairment on more complex BSL sentences, especially those in which grammatical constructions are used to encode negation, noun–verb distinctions, spatial verbs, and classifiers. These constructions encode meanings through morphosyntactic rules. Interestingly, and in contrast to hearing children with SLI, Paul's phonology was considered age-appropriate. Thus Paul's language profile is characterized as intact phonology and lexicon but with impaired grammar reception and production. Paul's greatest areas of difficulty were with polymorphemic constructions such as agreement morphology and the classifier system. The existence of a version of SLI appearing in a signed language provides evidence that SLI may be a modality-independent impairment in complex language use, but one in which the particular characteristics of the language in question may show specific vulnerabilities. For example, in spoken language SLI may affect both phonology and morphosyntax, while in a signed language the timing characteristic of sign articulation (i.e., phonology) is less perilous, whereas morphosyntax, which is heavily represented in a variety of constructions, remains vulnerable in sign language SLI.

Language disorders, whether acute or developmentally based, affect not only hearing users of spoken languages but users of signed languages as well. By comparing the manifestation of language disorders across users of disparate languages and disparate modalities of expression provides powerful means to determine the causal mechanisms involved in language pathology.

Abstract

This article presents an overview of psychological and neural aspects of sign languages. A brief discussion of cultural and linguistic issues of deafness and the structure of American Sign Language (ASL) provide a framework to understand findings from developmental psychology, psycholinguistics, cognitive psychology, and neuropsychological studies. Signed languages are naturally occurring human languages of deaf communities. Sign language acquisition follows a developmental trajectory similar to spoken languages. The recognition of a sign is influenced by the formational properties of sign language structure and occurs faster than spoken language recognition. While signs are articulated slower than spoken words, the proposition rate for sign and speech is the same. Memory for signs exhibits patterns of interference and forgetting that are similar to those found for speech. Studies of attention and perception indicate that the early use of sign language may enhance certain aspects of nonlanguage visual perception, such as the perception of motion. Neuropsychological and functional imaging studies show that left hemisphere regions are important in both sign and spoken language processing. Left hemisphere damage produces aphasia in signers. The existence of languages expressed in different modalities (i.e., oral–aural, manual–visual) provides a unique opportunity to explore and distinguish those properties shared by all human languages from those that arise in response to the modality in which the language is expressed.

Signed languages of the deaf are naturally occurring human languages. The existence of languages expressed in different modalities (i.e., oral–aural, manual–visual) provides a unique opportunity to explore and distinguish those properties shared by all human languages from those that arise in response to the modality in which the language is expressed. Despite the differences in language form, signed languages possess formal linguistic properties found in spoken languages. Sign language acquisition follows a developmental trajectory similar to spoken languages. Memory for signs exhibits patterns of interference and forgetting that are similar to those found for speech. Early use of sign language may enhance certain aspects of nonlanguage visual perception. Neuropsychological studies show that left hemisphere regions are important in both spoken and sign language processing.

Linguistic Principles of American Sign Language

Language and Deaf Culture

Sign languages are naturally occurring manual languages that arise in communities of deaf individuals. These manual communication systems are fully expressive, systematic human languages and are not merely conventionalized systems of pantomime or manual codifications of a spoken language. Many types of deafness are inheritable and it is not unusual to find isolated communities of deaf individuals, who have developed complex manual languages (Groce, 1985). The term Deaf Community has been used to describe a sociolinguistic entity that plays a crucial role in a deaf person's exposure to and acceptance of sign language (Padden and Humphries, 1988). American Sign Language (ASL), used by members of the Deaf community in the USA and Canada, is only one of many sign languages of the world, but it is the one that has been studied most extensively.

Structure of ASL

A sign consists of a hand configuration that travels about a movement path and is directed to or about a specific body location. Sign languages differ from one another in the inventories and compositions of handshapes, movements, and locations used to signal linguistic contrasts just as spoken language differ from one another in the selection of sounds used, and how those sounds are organized into words. Many sign languages incorporate a subsystem in which orthographic symbols used in the surrounding spoken language communities are represented manually on the hands. One example is the American English manual alphabet, which is produced on one hand and allows users of ASL to represent English lexical items.

All human languages, whether spoken or signed, exhibit levels of structure that govern the composition and formation of word forms and specify how words combine into sentences. In formal linguistic analyses, these structural levels are referred to as phonology, morphology, and the syntax of the language. In this context, phonological organization refers to the patterning of the abstract formational units of a natural language (Coulter and Anderson, 1993). Compared to spoken languages in which contrastive units (for example, phonemes) are largely arranged in a linear fashion, signed languages exhibit simultaneous layering of information. For example, in a sign, a handshape will co-occur with, rather than follow sequentially, a distinct movement pattern.

ASL exhibits complex morphology. Morphological markings in ASL are expressed as dynamic movement patterns overlaid on a more basic sign form. These nested morphological forms stand in contrast to the linear suffixation common in spoken languages (Klima and Bellugi, 1979). The prevalence of

simultaneous layering of phonological content and the nested morphological devices observed across many different sign languages likely reflect an influence of modality on the realization of linguistic structure. Thus the shape of human languages reflects the constraints and affordances imposed by the articulator systems involved in transmission of the signal (i.e., oral vs manual) and the receptive mechanisms for decoding the signal (i.e., auditory vs visual).

A unique property of ASL linguistic structure is the reliance upon visuospatial mechanisms to signal linguistic contrasts and relations. One example concerns the use of facial expressions in ASL. In ASL, certain syntactic and adverbial constructions are marked by specific and obligatory facial expressions (Liddell, 1980). These linguistic facial expressions differ significantly in appearance and execution of affective facial expressions. A second example concerns the use of inflectional morphology to express subject and object relationships. At the syntactic level, nominals introduced into the discourse are assigned arbitrary reference points along a horizontal plane in the signing space. Signs with pronominal function are directed toward these points, and the class of verbs that require subject/object agreement obligatorily move between these points (Lillo-Martin and Klima, 1990). Thus, whereas many spoken languages represent grammatical functions through case marking or linear ordering, in ASL grammatical function is expressed through spatial mechanisms. This same system of spatial reference, when used across sentences, serves as a means of discourse cohesion (Winston, 1995).

Sign Language Acquisition

Children exposed to signed languages from birth acquire these languages on a similar maturational timetable as children exposed to spoken languages (Meier, 1991). Prelinguistic infants, whether normally hearing or deaf, engage in vocal play commonly known as babbling. Recent research has shown that prelinguistic gestural play referred to as manual babbling will accompany vocal babbling. There appear to be significant continuities between prelinguistic gesture and early signs in deaf children exposed to ASL, though questions remain as to whether manual babbling is constrained by predominantly motoric or linguistic factors (Cheek et al., 2001; Petitto and Marantette, 1991).

Between 10 and 12 months of age, children reared in signing homes begin to produce their first signs, with two-sign combinations appearing at approximately 18 months. Some research has suggested a precocious early vocabulary development in signing children. However, these reports are likely to be a reflection of parents' and experimenters' earlier recognition of signs compared to words rather than underlying differences in development of symbolic capacities of signing and speaking children.

Signing infants produce the same range of grammatical errors in signing that have been documented for spoken language, including phonological substitutions, morphological overregularizations, and anaphoric referencing confusions (Petitto, 2000). For example, in the phonological domain a deaf child will often use only a subset of the handshapes found in the adult inventory, opting for a simpler set of 'unmarked' handshapes. This is similar to the restricted range of consonant usage common in children acquiring a spoken language.

Psycholinguistic Aspects of Sign Language

Psycholinguistic studies of ASL have examined how the different signaling characteristics of the language impact transmission and recognition. Signs take longer to produce than comparable word forms. The average number of words per second in running speech is about 4–5, compared with 2–3 signs per second in fluent signing. However, despite differences in word transmission rate, the proposition rate for speech and sign is the same, roughly one proposition every 1–2 s. Compare, for example, the English phrase 'I have already been to California' with the ASL equivalent, which can be succinctly signed using three monosyllabic signs, glossed as *finish touch california*.

Sign Recognition

Studies of sign recognition have examined how signs are recognized in time. Recognition appears to follow a systematic pattern in which information about the location of the sign is reliably identified first, followed by handshape information and finally the movement. Identification of the movement reliably leads to the identification of the sign. Interestingly, despite the slower articulation of a sign compared to a word, sign recognition appears to be faster than word recognition. Specifically, it has been observed that proportionally less of the signal needs to be processed in order to uniquely identify a sign compared to a spoken word. For example, one study reports that only 240 ms or 35% of a sign has to be seen before a sign is identified (Emmorey and Corina, 1990). In comparable studies of spoken English, Grosjean (1980) reports that 330 ms or 83% of a word has to be heard before a word can be identified. This finding is due, in part, to the simultaneous patterning of phonological information in signs compared to the more linear patterning of phonological information characteristic of spoken languages. These structural differences in turn have implications for the organization of lexical neighborhoods. Spoken languages, such as English, may have many words that share in their initial phonological structures (tram, tramp, trampoline, etc.) leading to greater coactivation (and thus longer processing time) during word recognition. In contrast, ASL sign forms are often formationally quite distinct from one another, permitting quicker selection of a lexical unique entry.

Memory for Signs

Efforts to explore how the demands of sign language processing influence memory and attention have led to several significant findings. Early studies of memory for lists of signs report classic patterns of forgetting and interference, including serial position effects of primacy and recency (i.e., signs at the beginning and the end of a list are better remembered than items in the middle). Likewise, when sign lists are composed of phonologically similar sign forms, signers exhibit poorer recall (Klima and Bellugi, 1979). This result is similar to what has been

reported for users of spoken language, where subjects exhibit poorer memory for lists of similarly sounding words (Conrad and Hull, 1964). These findings indicate that signs, like words, are encoded into short-term memory in a phonological or articulatory code rather than in a semantic code.

More recent work has assessed whether Baddeley's (1986) working memory model pertains to sign language processing. This model includes components that encode linguistic and visuospatial information as well as a central executive which mediates between immediate and long-term memory. Given the spatial nature of the sign signal, the question of which working memory component(s) is engaged during sign language processing is particularly interesting. Wilson and Emmorey (2000) have shown word-length effects in signs; it is easier to maintain a cohort of short signs (monosyllabic signs) than long signs (polysyllabic signs) in working memory. They also report effects of 'articulatory suppression.' In these studies, requiring a signer to produce repetitive, signlike hand movements while encoding and maintaining signs in memory has a detrimental effect on aspects of recall. Once again, analogous effects are known to exist for spoken languages and these phenomena provide support for a multicomponent model of linguistic working memory that includes both an articulatory loop and a phonological store. Finally, under some circumstances deaf signers are able to utilize linguistically relevant spatial information to encode signs, suggesting the engagement of a visuospatial component of working memory.

Perception and Attention

Recent experiments with native users of signed languages have shown that experience with a visual sign language may improve or alter visual perception of nonlanguage stimuli. For example, compared to hearing nonsigners, deaf signers have been shown to possess enhanced or altered perception along several visual dimensions, such as motion processing (Bosworth and Dobkins, 1999), mental rotation, and processing of facial features (Emmorey, 2001). For example, the ability to detect and attend selectively to peripheral, but not central, targets in vision is enhanced in signers (Neville, 1991). Consistent with this finding is evidence for increased functional connectivity in neural areas mediating peripheral visual motion in the deaf (Bavelier et al., 2000).

As motion processing, mental rotation, and facial processing underlie aspects of sign language comprehension, these perceptual changes have been attributed to experience with sign language. Moreover, several of these studies have reported such enhancements in hearing signers raised in deaf signing households. These findings provide further evidence that these visual perception enhancements are related to the acquisition of a visual manual language, and are not due to compensatory mechanisms developed as a result of auditory deprivation.

Neural Organization of Signed Language

Hemispheric Specialization

One of the most significant findings in neuropsychology is that the two cerebral hemispheres show complementary functional specialization, whereby the left hemisphere mediates language behaviors while the right hemisphere mediates visuospatial abilities. As noted, signed languages make significant use of visuospatial mechanisms to convey linguistic information. Thus sign languages exhibit properties for which each of the cerebral hemispheres shows specialization. Neuropsychological studies of brain injured deaf signers and functional imaging studies of brain intact signers have provided insights into the neural systems underlying sign language processing.

Aphasia in Signed Language

Aphasia refers to acquired impairments in the use of language following damage to the perisylvian region of the left hemisphere. Neuropsychological case studies of deaf signers convincingly demonstrate that aphasia in signed language is also found after left hemisphere perisylvian damage (Poizner et al., 1987). Moreover, within the left hemisphere, production and comprehension impairments follow the well-established anterior versus posterior dichotomy. Studies have documented that frontal anterior damage leads to Broca-like sign aphasia. In these cases, normal fluent signing is reduced to effortful, single-sign, 'telegraphic' output with little morphological complexity (such as verb agreement). Comprehension, however, is left largely intact. Wernicke-like sign aphasia following damage to the posterior third of the perisylvian region presents with fluent but often semantically opaque output and comprehension also suffers. In cases of left hemisphere damage, the occurrence of sign language paraphasias may be observed. Paraphasia may be formationally disordered (for example, substituting an incorrect handshape) or semantically disordered (producing a word that is semantically related to the intended form). These investigations serve to underscore the importance of left hemisphere structures for the mediation of signed languages and illustrate that sign language breakdown is not haphazard, but rather honors linguist boundaries (Corina, 2000).

The effects of cortical damage to primary language areas that result in aphasic disturbance can be differentiated from more general impairments of movement. For example, Parkinson's disease leads to errors involving timing, scope, and precision of general movements including, but not limited to, those involved in speech and signing. These errors produce phonetic disruptions in signing, rather than higher-level phonemic disruptions that are apparent in aphasic signing (Corina, 1999).

Apraxia is defined as an impairment of the execution of a learned movement (e.g., saluting, knowing how to work a knife and fork). Lesions associated with the left inferior parietal lobe result in an inability to perform and comprehend gestures (Gonzalez Rothi and Heilman, 1997). Convincing dissociations of sign language impairment with well-preserved praxic abilities have been reported. In one case, a subject with marked sign language aphasia affecting both production and comprehension produced unencumbered pantomime. Moreover, both comprehension and production of pantomime were found to be better preserved than was sign language. These data indicate that language impairments following left hemisphere damage are not attributable to undifferentiated symbolic impairments and demonstrate that ASL is not simply an elaborate pantomimic system.

Role of the Right Hemisphere in ASL

Studies of signers with right hemisphere damage (RHD) have reported significant visuospatial disruption in nonlinguistic domains (e.g., face processing, drawing, block construction, route finding, etc.) but have reported only minimal language disruption. Problems in the organization of discourse have been observed in RHD signers, as have also been reported in users of spoken languages. More controversial are the influences of visuospatial impairment in the use of highly spatialized components of the language, such as complex verb agreement and the classifier system. Further work is needed to understand whether these infrequently reported impairments (both in comprehension and production) reflect core linguistic deficits or rather reflect secondary effects of impaired visuospatial processing.

Functional Imaging

Recent studies using functional brain imaging have explored the neural organization of language in users of signed languages. These studies have consistently found participation of classic left hemisphere perisylvian language areas in the mediation of sign language in profoundly deaf, lifelong signers. For example, positron emission tomography studies of production in British Sign Language (McGuire et al., 1997) and Langue des Signes Quebecoise (Petitto et al., 2000) reported deaf subjects activated left inferior frontal regions, regions similar to those that mediate speech in hearing subjects. Researchers using functional magnetic resonance imaging techniques in investigating comprehension of ASL in deaf and hearing native users of signed language have shown significant activations in frontal opercular areas (including Broca's area and dorsolateral prefrontal cortex) as well as in posterior temporal areas (such as Wernicke's area and the angular gyrus) (Neville et al., 1998). Also reported was extensive activation in right hemisphere regions. Subsequent studies have conferred that aspects of the right posterior hemisphere activation appear to be unique to sign language processing and present only in signers who acquired sign language from birth (Newman et al., 1998).

Investigations of psychological and neural aspects of signing reveal strong commonalities in the development and cognitive processing of signed and spoken languages despite major differences in the surface form of these languages. Early exposure to a sign language may lead to the enhancements in the specific neural systems underlying visual processing. There appears to be a strong biological predisposition for left hemisphere structures in the mediation of language, regardless of the modality of expression.

Abstract

Signal detection theory (SDT) provides a framework for the quantification of sensitivity in sensory-perceptual tasks, and can be applied to other real-world applications. The measure d' quantifies the resolving power of the perceptual system, while controlling for the response bias of the judge. Given the same stimuli and judge, resolving power should be invariant irrespective of the psychophysical task employed. SDT models can unify results over different tasks, and different decision strategies – the mapping of perceptual information to a response – allowed for by some tasks.

Signal detection theory (SDT) provides a framework for the analysis of performance in tasks for which stimuli (or events) are confusable. SDT can be applied to applications in engineering, the assessment of sensory or cognitive performance in the fields of psychology and sensory evaluation, the assessment of diagnostic accuracy in the medical sciences, and forecasting in areas such as meteorology.

A distinction is made between two fundamental paradigms: discrimination and detection. The discrimination paradigm quantifies how well individuals (or systems) can resolve the difference between two stimuli, whereas the detection paradigm quantifies an individual's ability to resolve the difference between the presence and absence of a stimulus. Much of the early work in SDT focused on detection. Given that the general application of SDT to both paradigms is essentially the same, the remainder of this article will focus primarily on discrimination.

The Single-Interval Task

The single-interval task is the standard experimental design in SDT. It is also known as the Yes–No task, and the A–Not-A task, in the psychophysics and sensory evaluation literature, respectively. On a trial, one of two stimuli (S_1 or S_2) is presented to the judge, who must indicate whether S_1 or S_2 was presented. Table 1 gives the four possible outcomes for a trial when the judge issues a binary response (e.g., 'S_2' or 'S_1;' 'yes' or 'no;' 'A' or 'Not-A'). Hits and correct rejections are correct responses, and misses and false alarms are incorrect responses. The medical and epidemiology literature uses a different terminology, also given in Table 1.

Consider for Example 1 an auditory experiment designed to measure the ability of a judge to discriminate the difference in amplitude of two tones, S_1 and S_2, with a relatively lower and higher intensity, respectively. On a trial, either S_1 or S_2 is presented to the judge, who must indicate which was presented. If the intensity difference between the tones is small, the sensory evidence upon which the judgment is made will be confusable; that is, across repeated presentations, the sensory magnitude arising from S_1 will sometimes be lower than that for S_2, and at other times it will be higher. This variation in sensory magnitude is a consequence of many factors, one of which is moment-to-moment variability in activity within the sensory system. The degree of sensory variability relative to the difference between the stimuli limits the performance of the judge.

This sensory variability is attributed to the addition of random noise, often called sensory noise, to the presented stimulus. The original terminology of SDT arose from this viewpoint. In a detection task, where a low-level stimulus either is or is not presented on a trial, the stimulus is called the signal. When no stimulus is presented, sensory noise still influences the detection decision; consequently, trials on which stimuli are not presented are called noise trials. When the signal is presented, the sensory noise is also present; hence, these are called signal-plus-noise trials. The combination of sensory noise and stimulus-related neural activity used by the judge in decision making is the sensory evidence.

Returning to Example 1, consider the data in Table 2, which details the frequency of each outcome from the presentation of S_1 and S_2, each 50 times. The frequencies are typically converted to rates; for example, the hit rate, H, is obtained by dividing the frequency of hits by the number of S_2

Table 1 Four outcomes of a trial in the single-interval task as named in psychology (first entry) and medicine (second entry)

	Binary response	
Stimulus	'S_2'	'S_1'
S_2	Hit True positive (sensitivity)	Miss False negative
S_1	False alarm False positive	Correct rejection True negative (specificity)

Table 2 Frequencies (top entry) and rates (bottom entry) of each outcome for Example 1, with 50 presentations each of S_1 and S_2

	Binary response	
Stimulus	'S_2'	'S_1'
S_2	Hits = 37 $H = .74$	Misses = 13 $M = .26$
S_1	False alarms = 18 $F = .36$	Correct rejections = 32 CR = .64

presentations ($H = 37/50 = .74$). The divisor for the false-alarm (F) and correct-rejection (CR) rates would be the number of S_1 presentations. The rates for the two outcomes for S_1 and two outcomes for S_2 each sum to one; thus, the experiment can be summarized by just two rates. Tradition is to use H and F.

The Standard SDT Model

A common assumption about the sensory noise is that it is normally distributed. Another less common assumption is that the variability of the sensory noise is independent of the difference between S_1 and S_2; this is the so-called equal-variance assumption. These two assumptions underpin the standard version of the SDT model, sometimes called the normal–normal equal-variance model (NEV). Figure 1 depicts the decision space for this model. The two distributions represent the sensory evidence arising from S_1 and S_2. In perceptual tasks, this evidence typically represents the moment-to-moment variation in the neural representation of the stimuli. However, it can also represent physical variation in S_1 and S_2 across presentations; this is typical of class-discrimination experiments, in which S_1 and S_2 are drawn from two sets of stimuli (e.g., old and new words in a word recognition experiment), or experiments in which random variation is deliberately added to the stimuli. In medical applications, this evidence can represent the magnitude of a physical measure, sometimes called a biomarker, which may have use in diagnosing the presence (S_2) or absence (S_1) of an abnormality. Such measures commonly show a distribution of magnitudes across patients, or time.

Faced with this evidence, a judge must make a decision. The solid vertical line in Figure 1 is a decision criterion. Evidence that falls above the criterion leads to the response 'S_2' and results in hits and false alarms. 'S_1' is the response given to evidence that falls below the criterion, leading to misses and correct rejections. The areas under the distributions above and below the criterion provide the four outcome rates.

Sensitivity and Response Bias

The most common formulation of the model given in Figure 1 has two parameters. The first, d', is the difference between the means of the two standardized distributions, and represents the ability of the perceptual system to distinguish between S_1 and S_2. The second, x_c, is the value of the evidence axis on which the criterion is located, and represents the judge's propensity for responding one way or the other. x_c is rarely used directly. Instead, a parameter, c, is defined as the distance of the criterion from a point midway between the two distributions, hence $c = x_c - d'/2$. In Figure 1, $d' = 1$ and $x_c = -.69$; hence $c = -1.19$. The shaded areas yield $F = .75$ and $H = .95$. When estimated from data, d' and c are measures of sensitivity and response bias, respectively.

The standard SDT model can now be applied to the data from Example 1. The two parameters can be estimated using the equations $d' = z(H) - z(F)$ and $c = -{}^1/_2\,[z(H) + z(F)]$, where $z(\bullet)$ is the inverse-normal transform. For Example 1, $d' = z(.74) - z(.36) = .64 - (-.36) = 1.00$, and $c = -{}^1/_2\,[z(.74) + z(.36)] = -.14$. The distributions in Figure 1 are appropriate for these data, but with the criterion indicated by the dashed vertical line. For binary data, the model is saturated, and goodness-of-fit (GOF) cannot be assessed.

A common method used to increase the available degrees of freedom of the model is to increase the number of response options, often referred to as confidence ratings. This adaptation of the single-interval task provides more than one F, H pair from a single experiment. For Example 2, consider the same experiment as before, except that now the judge responds on a six-point confidence-rating scale. A response of '1' could indicate certainty that the stimulus presented was S_2, while '6' could indicate certainty that it was S_1. Other values of response indicate levels of certainty between these two end points; for example, '4' may indicate 'uncertain, but think it was S_1. Table 3 shows the frequencies of each response to the presentation of S_1 and S_2. F and H for each response are obtained by cumulating frequencies for all response ratings up to the target response, and then dividing by the total number of presentations of S_2 for H and of S_1 for F. This results in $n_r - 1$ estimates of F, H pairs, where n_r is the number of ratings used on the response scale. The determination of measures of sensitivity and bias from these data benefits from the introduction of a different representation of the model illustrated in Figure 1.

Figure 1 Decision space for the single-interval task.

Receiver Operating Characteristic Curves

The receiver operating characteristic (ROC) curve is obtained by setting d' to a fixed value and varying the criterion, c, over all

Table 3 Frequency of each rating response given to presentations of S_1 and S_2

		'S_2'		Rating response			'S_1'
Stimulus		1	2	3	4	5	6
S_2	Frequency	22	15	6	3	3	1
	H	.44	.74	.86	.92	.98	1.00
S_1	Frequency	5	11	13	10	8	3
	F	.10	.32	.58	.78	.94	1.00

Accumulation of frequencies from left to right, and division of each sum by the number of presentations (50) gives the estimated values of F and H.

Figure 2 ROC curve for the binary-response data of Example 1.

Figure 3 ROC curve for the rating-response data of Example 2.

possible values. Each value of c yields an F, H pair. The ROC curve is a plot of H against F in the unit square. The ROC curve illustrated in Figure 2 has $d' = 1$. Any point on the curve represents a particular value of the criterion. The circle, at $F = .36$, $H = .74$, corresponds to $c = -.14$ and represents the data from Example 1.

The shape of the ROC curve for the NEV model is concave downward, symmetrical about the minor diagonal of the ROC square, and passes through the points (0,0) and (1,1). The concavity of the ROC curve is proportional to d', and while d' itself is not easily quantifiable directly from the ROC curve, this relationship suggests another measure of sensitivity, the area under the ROC curve, A_z (sometimes referred to as area under the curve; AUC). A_z can range between half and one, and is equal to $\Phi(d'/\sqrt{2})$, where $\Phi(\bullet)$ is the standard normal distribution function. Chance performance corresponds to $d' = 0$ and $A_z = .5$, whereas perfect performance has $d' = \infty$ and $A_z = 1$.

Another index of sensitivity, proportion correct ($p(c)$), can be determined from the ROC space. It is the area under an ROC curve formed by straight lines that join the points (0,0), (F,H), and (1,1), and is indicated by the shaded area in Figure 2. Determination of $p(c)$ in terms of F and H using simple geometrical principles yields $p(c) = {}^1/_2\,[H + (1-F)]$. Given that $1-F$ is the CR rate, it is clear that $p(c)$ is half the sum of the proportions for each type of correct response. For the case of Example 1, $p(c)$ is .69. Points at different locations on the same ROC curve will yield different values of $p(c)$, demonstrating that $p(c)$ is not bias-free, unlike d', or the full area under the ROC curve, A_z, which for Example 1 is .76.

The points in Figure 3 define the empirical ROC based on the data from Example 2 (see Table 3). No single ROC curve based on the NEV model could pass through all points. Thus, the best-fitting curve must be determined; note that both F and H are subject to sampling variability.

There are two basic approaches to fitting ROC curves to empirical ROC data. The ordinal regression approach, which models the probability frequencies of ratings, is more widespread, and can be traced back at least to the algorithms published by Dorfman and Alf (1969). The direct modeling approach is a more recent formulation. It directly models the relationship between the frequency of ratings for S_1 and S_2 (Pepe, 2003). Both approaches allow for covariates in the models. While covariate modeling in ROC analysis appears infrequently in the psychological literature, it is prevalent in medical literature.

The ROC curve in Figure 3 was fitted using the ordinal regression approach. The estimate of d' is .98 and A_z is .76. There are also five criterial estimates ($c = -1.91, -1.16, -0.68, -0.10, 0.69$). The GOF of the curve can be assessed using Pearson's chi-square (χ^2). In this case, $\chi^2 = 2.71$, there are 4 degrees of freedom, and yields a probability of .608. This probability – if the standard assumptions are met for χ^2 – can be interpreted as the probability that the data arose from the model, given that the model is correct. In practice, small probabilities (e.g., $p < .001$) are employed to reject a model (Press et al., 1992).

For rating data, $p(c)$ can be generalized by constructing an ROC curve with linear segments, as illustrated in Figure 3, and then calculating the area under it. The two most commonly used names for this measure are A_g and the R-index. This index is equivalent to the Mann–Whitney U statistic (Bamber, 1975). For Example 2, A_g is .75, which in this case is close to A_z at .76.

Alternative Distribution Assumptions

The NEV model is but one valid alternative. A natural generalization of this model is the normal–normal unequal-variance (NUEV) model. This model allows the variance of the S_2 distribution to differ from one (assuming a standardized S_1 distribution), or more generally, the ratio of the variances of S_1 to S_2 to vary from one. NUEV ROC curves can be asymmetrical about the minor diagonal of the ROC square, whereas NEV ROCs are symmetrical. Consequently, the NUEV model

can fit a broader variety of data. However, this model can be problematic.

ROC curves have two major properties. An ROC curve that touches the unit square only at the points (0,0) and (1,1) is said to be regular, and one with a monotonic-decreasing slope as F increases is said to be proper. The majority of empirical ROCs support the premise that ROC curves should be both regular and proper. NUEV ROC curves are regular, but are not proper. Despite this impediment, NUEV ROCs are the most prevalent type reported in the literature. A proper ROC curve can be derived from the NUEV model by transforming the decision variable so that it is monotonic with likelihood ratio (Egan, 1975).

It is not necessary to assume that the underlying distributions for ROC curves (or SDT in general) are Gaussian, as any distribution can replace the Gaussian. A common alternative is the logistic distribution, which affords much simpler mathematics than the Gaussian. In addition, the logistic ROC curve is very similar to the Gaussian ROC curve, so similar that it is difficult to choose which is more appropriate from experimentation. In addition, logistic distributions are strongly connected to choice theory (Luce, 1959) and have strong justification for use in the analysis of categorical data, such as collected in SDT research (Agresti, 2007).

Distributions may be selected based on the known variability in the physical stimulus. If this variability is sufficiently large it will swamp the internal sensory variability, meaning that the evidence upon which decisions are made primarily derives its variation from the physical stimulus. Examples of this include Rayleigh distributions as the basis for the discrimination of auditory Rayleigh noise; χ^2 distributions for the discrimination of auditory Gaussian noise; or Poisson distributions for the detection of light (Egan, 1975). The gamma distribution has received attention in ROC analysis in the medical sciences (Dorfman et al., 1997). Gamma ROCs are both proper and regular. In addition, the gamma distribution holds several special relationships to other distributions, including beta, exponential, and χ^2, all of which can be shown to be special cases of gamma.

Multiple-Interval Tasks

The single-interval task is but one of many paradigms. If S_1 and S_2 are presented consecutively on a trial, the judge could be asked to identify which was S_2, the first or the second stimulus. This is the two-alternative forced-choice (2AFC) task. This task poses the opportunity to consider how a judge maps the sensory evidence onto a response. For the single-interval task, the judge divides the sensory evidence into two 'sections' using the criterion and attaches a response to each section. This mapping of evidence to response is termed a decision strategy. In 2AFC, a judge can employ two distinct decision strategies. The judge could determine the difference between the sensory evidence from the two presentations, and then this difference could be compared to a criterion. If the difference is greater than the criterion, the judge responds 'second,' otherwise 'first.' If the criterion is zero (representing an equal weighting of both sources of evidence), this amounts to choosing the presentation with the greatest magnitude of sensory evidence. This is the decision strategy (DS). An alternative strategy is for the judge to estimate separately the likelihood that each presentation was either S_1 or S_2, and then to compare the ratio of these two likelihoods (second over first presentation) to a criterion. Assuming the criterion is set to one (representing equal evidence either way), if the ratio of likelihoods is greater than one, the judge responds 'second,' otherwise 'first.' This is called the independent-observations decision strategy (IOS). For 2AFC, responses based on any choice of criterion under the DS can be matched exactly by a distinct criterion under the IOS to yield the same performance. The ROC curves based on each decision strategy are identical. For this reason, attention to the decision strategy adopted by a judge is usually not required when determining performance in 2AFC.

Now consider another two-stimulus task. On any trial one of the following sequences of stimuli are presented to the judge: $<S_1, S_1>$, $<S_2, S_2>$, $<S_1, S_2>$, or $<S_2, S_1>$. The judge then indicates whether the two stimuli presented were the 'same' or 'different.' This is the standard same–different task. The judge can employ the DS or the IOS in this task as well. For the DS the judge determines the difference between the sensory evidence arising from each presented stimulus. If this difference is less than a criterion value, the judge responds 'same,' otherwise 'different.' For the IOS, the judge should respond 'same' if both stimuli presented on a trial were more likely to stem from S_1 than from S_2, or if both were more likely to stem from S_2 than from S_1; otherwise respond 'different.'

ROC curves can be generated for the same–different experiment by defining H and F as the probabilities of responding 'different' and 'same,' respectively, given that the stimuli were in fact different. The ROC curves for each decision strategy take on a different form. Figure 4 illustrates ROC curves for the case where $d' = 2$. For the DS, the curves are asymmetrical about the minor diagonal, whereas for the IOS the curves are symmetrical. This indicates that the decisions made under each strategy, given the same values of sensory evidence, are not always the same. Figure 4 also

Figure 4 ROC curves ($d' = 2$) for two decision strategies in the same–different task.

shows that the value of H, at all values of F, is higher for the IOS ROC curve than that for the DS. Not only do judges sometimes give different responses under the two strategies, but when the responses do differ, the response from the IOS judgment is more often correct.

The IOS, based on the likelihood ratio, is the optimal decision strategy in a statistical sense, and of all possible strategies yield the highest proportion of correct responses (Green and Swets, 1966). In contrast, the DS is a suboptimal decision strategy. The difference in performance can be substantial; a 20% discrepancy is common. This has practical ramifications. It is not possible to estimate an accurate value of d' for the same–different experiment unless the decision strategy used by the judge is known. Visual research on the shape of the same–different ROC suggests that the DS is used almost exclusively for simple visual stimuli, whereas the IOS is used with more complex visual stimuli (Irwin and Francis, 1995). However, recent research suggests that this pattern may not apply to all modalities; specifically, the IOS may be used for simple gustatory stimuli.

Same–different is not the only task to yield different levels of performance when different decision strategies are used. Tasks belonging to the reminder paradigm also show different levels of performance. These include the single-interval and 2AFC reminder tasks – identical to their namesakes already discussed, except that S_1 is presented at the start of every trial. The ABX experiment, sometimes referred to as matching-to-sample, is another example.

The same–different task shows a difference in shape between the ROC curves derived from each decision strategy. Other tasks show only a difference in the area under the ROC curves for each strategy. This makes it more difficult to determine which strategy a judge uses for these tasks. The most common approach hinges on one of the central tenets of SDT; a valid measure of sensitivity should obtain the same estimate irrespective of the method used to obtain it. In the NEV SDT framework, d' is that measure. Estimates of d' can be obtained under the assumption of the various decision strategies available in a task and can then be compared to d' estimates obtained using a different task for which there is less uncertainty about the decision strategy adopted. Usual candidates for this comparison are the single-interval task, which has only one candidate decision strategy, or the 2AFC task, which has two candidate strategies, but with each theoretically producing the same outcomes (Macmillan and Creelman, 2005; Hautus et al., 2009). This approach may be confounded by factors not yet incorporated into the SDT framework that can differentially affect performance across psychophysical tasks. For example, memory effects (decay or interference) are likely to be larger in tasks with more stimulus presentations per trial. Memory effects on d' have been demonstrated in several studies that manipulated the interstimulus interval in the 2AFC task (Macmillan and Creelman, 2005).

Multiple Stimuli Varying along One Dimension

Consideration, thus far, has been given to discrimination between two stimuli (or two classes of stimuli). The extension of SDT to more than two stimuli is easy when those stimuli are located along a single physical dimension (e.g., sound intensity), or more generally, change along more than one physical dimension but only one perceptual dimension (e.g., loudness). This form of task, with n stimuli and m response options ($m \leq n$), is typically called a classification task. The representation of the decision space is analogous to that of Figure 1. The number of distributions equals n (in Figure 1, $n = 2$), the number of stimuli employed in the experiment, except there are now more than two stimuli. d' can be determined, for any pair of stimuli, as the distance between their means (assuming the NEV model).

Performance on classification tasks turns out to be worse than on two-stimulus discrimination tasks. An explanation is that performance is limited in discrimination tasks primarily by the resolving power of the sensory system, whereas classification tasks are also influenced by context coding, processes involved in assigning labels, which add judgmental variance to the sensory variance (Durlach and Braida, 1969). In an experiment that contrasted these two approaches for determining sensitivity to experimental pain, the classification task ($n = m = 6$) produced estimates of sensitivity over four times less than the discrimination task (Irwin et al., 1994). Similar studies in other modalities confirm the degraded performance due to additional noise associated with decision processes in classification tasks.

Multidimensional Detection Theory

The tasks previously described that involve two stimuli (or classes of stimuli) are appropriate for stimuli that are unidimensional, as well as for stimuli that can vary along more than one dimension (e.g., intensity and frequency). The tasks in the previous section that involve more than two stimuli are only applicable when those stimuli are located along the same single dimension (e.g., intensity). Multidimensional detection theory is the extension of SDT to the case of more than two stimuli, each of which can vary over more than one physical or perceptual dimension.

Multidimensional detection theory can address issues related to the dimensionality of sensory evidence and the degree of independence of criterion placement on those dimensions. Three forms of independence are of note: perceptual independence, perceptual separability, and decisional separability. Perceptual independence refers to the relationship between the physical dimensionality of a stimulus and the sensory evidence arising thereof. For example, if the intensity of a white light is increased gradually the perception of brightness, as expected, increases, but so too does the perceived hue; the light looks more yellow. Here, a single physical dimension gives rise to two dependent perceptual dimensions. When there is more than one physical dimension, perceptual separability holds if the level of one stimulus dimension has no effect on the sensory evidence arising from other dimensions. Stimuli that vary along the physical dimensions of electromagnetic wavelength (hue) and shape give rise to perceptually separable dimensions. Decisional separability holds if the judge's criterion for the sensory evidence relating to one stimulus dimension is not influenced by the sensory evidence arising from other dimensions (Ashby, 1992).

Abstract

Detection Theory is traced from its origins in engineering and statistical decision theory through to its adaptation in experimental psychology, medical diagnosis, and elsewhere. The original displacement of threshold notions is summarized, and early experiments establishing the theory, as well as some adaptations and extensions are described.

Introduction and Background

Signal Detection Theory, as the phrase is used in psychology, medical science, and in many other fields, refers to ways data are analyzed, where detection or identification of an input signal is required. These techniques have roots in the technology of identifying threat from enemy aircraft using RADAR during the World War II (WWII). The path from there to current applications is the task of this article.

The story, as it unfolds in the field of sensory psychology, involves in the first instance, problems of measuring the sensitivity of human visual and auditory systems. The story also involves quantifying the basis of the decisions that are made in conditions with uncertain or noisy input information. The application of Detection Theory involved a genuine revolution in the ways data in many fields are collected and analyzed. Signal Detection Theory has provided new ways to understand how sensory systems process their inputs.

An operator of an early RADAR console attempting to identify an aircraft, watching a display on a cathode ray tube, was faced with a prototypical detection problem. The display was covered with 'snow,' reflections from atmospheric features, and the results of random activity in the vacuum tube circuits processing signals passed from an antenna. This was the visual equivalent of the noise from an FM radio when not tuned to a strong station. Buried in this visual noise might have been a reflection from an aircraft. Noise might mock the signature of an aircraft, and noise might mask an important signal.

To overcome these problems, a first approach might be to increase the strength of the overall input to the RADAR console. However, amplification boosted noise to the same degree as relevant signals. A more sophisticated approach arose, primarily, in the United States, at the Massachusetts Institute of Technology (MIT).

Subsequent to the end of WWII, and the end of tight security around theoretical work in the field, academically connected laboratories, such as those at MIT and the University of Michigan, published work describing ways to analyze faint, noise-contaminated signals. From the Research Laboratory of Electronics at MIT, van Meter and Middleton (1954) published their analysis of the problem of extracting a signal that is imbedded in noise. Davenport and Root (1958) provided a comprehensive text on the engineering issues surrounding signal extraction. At the University of Michigan, Peterson et al. (1954) addressed the same issues, arriving at some of the same theoretical findings, and built on them by adding consideration of the decision processes required. The technique involved two core ideas: detection should involve correlation of a known signal with the noise-masked input and the input signal could be fully characterized by sampling at a rate determined by the bandwidth of the noise and the duration of the observation.

A second part of the detection problem, when the input might or might not contain a signal, was to define the optimal basis for decision. Here, the authors showed that the *likelihood ratio* was the optimal basis for decision, the ratio of the likelihood that the input came from a signal in the noise to that of the noise alone, with no signal present. Such a signal analysis and subsequent decision was characterized by Peterson and Birdsall an *ideal observer*. The notion of an ideal observer looms large later in approaches to human perception and neurological processing.

These notions found their way into psychological laboratories and from there into a much wider community, starting with the Vision Research Laboratories at the University of Michigan.

Vision Research at Michigan

In the early 1950s, two graduate students were working in the Vision Research Laboratory, directed by H. Richard Blackwell. W. P. Tanner, Jr. (known as 'Spike') had spent WWII with the US Navy, working in an electronics facility. After the war, he obtained a Masters degree at the University of Florida and then went on to the PhD program at Michigan. John A. Swets had done his undergraduate degree at Michigan. Tanner, with a young family, was working on the side at the Vacuum Tube Laboratory in the Engineering School. He came into contact with graduate students there, Wes Peterson, an engineering student, and Ted Birdsall, a mathematician. Together they were developing their Theory of Signal Detectability; Tanner saw ways to apply some of their ideas in the experiments he was conducting in the Psychology Department, and Swets quickly saw the importance of this work.

The Vision Research Laboratory at Michigan was equipped with excellent stimulus-generating equipment, with full optical benches devoted to presenting simple visual stimuli focused on backlit screens. Control of experiments was mechanical/electrical; exact timing of stimulus presentation was electronic, and recording observers' responses was on mechanical

counters. Experiments were conducted in small light-proof theaters seating only two paid viewers who reported their responses using pushbuttons. This arrangement, fine stimulus control, with precise timing and response registration using state-of-the-art technology and with observer isolation formed the basic arrangement for psychophysical experimentation elsewhere.

This setting was put together by Blackwell with help from technicians, and with statisticians to formalize ways to analyze data (Blackwell et al., 1954). The aim was to understand how the visual system worked; how it could be studied and thresholds measured, in a fundamental sense.

In the 1950s, psychological theory and experiment were under the thrall of Behaviorism (Watson, 1925). Psychological theorists and experimenters took from Watson the notion that, since internal, cognitive experiential events could not be observed directly, they had no place in the field. Observed behavior was then all that was left for systematic, rigorous scientific study. Subjects in sensory experiments, for instance, could say 'yes' or 'no,' or the equivalent with a button press, and the processes that lead to that response were deemed outside the purview of the theorist.

However since the time of Fechner, the recognized founder of psychophysics (Fechner, 1860), it had been known that seeing a faint stimulus or hearing a faint sound was probabilistic; the 'threshold' was a statistical fiction, an arbitrary point on the continuous increasing function relating stimulus intensity to the proportion of 'yes' responses. That function increased from zero with no stimulus to 100% with a sufficiently large one. Usually, Osgood (1958) in his definitive textbook on experimental psychology captured the issue in Operational terms: "Thresholds only appear in the final statistical treatment of the data." And he concluded, "It is clear that the various psychophysical methods are not merely different ways of measuring the same thing."

Sometimes, however, observers responded 'yes' to an empty stimulus. Laboratory manuals suggested presenting the occasional blank stimulus to be sure that subjects were paying attention. A 'yes' response in this case was treated seriously; it should be treated as 'a lack of rigorous attention' that the observer should be 'waked up' (Titchener, 1901, pp. 103). This all-or-none view of sensory experience, that on any occasion sensory input triggered a sensation or not, the concept, at least on a trial-by-trial basis that an observer experienced a presented stimulus, or not, was at the heart of most approaches to psychophysical measurement.

Blackwell, in his laboratory, approached these problems with two important innovations. First, since observers were known sometimes to respond to blank presentations, called then, 'catch-trials,' they should be accepted as part of the data. Rather than presenting a catch-trial only rarely, as recommended by Titchener, catch-trials were made a regular occurrence, presented on as many as 50% of trials on a random basis. The assumption underlying the analysis of the data was that the observers simply or mistakenly sometimes said 'yes' on a catch-trial because of a mix-up in finger-to-button alignment, or desire to please the experimenter, or some other reason. Thus, the obtained percentage of 'yes' responses, made up of those supposedly actually experienced mixed with the other 'spurious' ones, should be 'corrected' to remove the improper ones. This was because there were a sufficient number of catch-trials to constitute a reliable estimate of how often the observer responded 'yes' when the stimulus had not been seen. The true psychometric function, relating percentage of seen signals to intensity would then go from zero to 100%, rather than, as the uncorrected data showed, starting at the 'false-alarm' rate of response to empty trials at zero stimulus intensity.

The second innovation in Blackwell's laboratory was to eliminate the problem of false alarms entirely, presenting to observers on each trial four successive time intervals, indicated by auditory markers. Only one of the intervals, randomly chosen, contained a visual signal. The observer was then required to indicate a best guess as to which of the four contained the stimulus. This four-alternative forced choice procedure, if the observer saw nothing, would yield a theoretical minimum 25% correct responses, the expected random performance for inability to see anything. So this was used as the 'correction' to make a psychometric function go from zero to 100%, instead of the obtained lower limit of 25% at zero stimulus intensity.

Another important predecessor of Detection Theory, Thurstone (1927) had suggested that the effects of stimuli to be compared were statistically distributed. The idea added by Detection Theory, which Thurstone and his followers missed, was that the dividing line between one response and the alternative could vary, chosen depending on aims of the subject in an experiment. Thurstone's model had the line between choice of one alternative and the other situated at the crossover point of the alternative statistical distributions, and not adjustable according to the situation and objectives of the observer.

The Original Experiments

Swets proceeded to apply notions from the theoretical structure of Peterson and Birdsall, in Blackwell's laboratory. Ongoing discussions with Tanner enriched the work and ultimately led to his PhD thesis being published (Tanner et al., 1956). Tanner's work in the laboratory, on detection of visual signals that were presented randomly over a spatial area, was never published; Tanner left the Vision Research Laboratory and moved to another Michigan laboratory, the Electronic Defense Group. There he established a hearing research laboratory with an active program of research on auditory function, publishing and supervising graduate students and postdoctoral fellows even though he himself did not yet have a doctoral degree.

Tanner and Swets showed that decisions in visual detection tasks appeared to be on the basis of statistically distributed inputs, where a signal added to a background simply moved the mean of an underlying distribution. Furthermore, the data showed that observers were able to evaluate sensory inputs on a continuum, a dimension which could be considered to correspond to Detectability Theory's likelihood ratio. These data questioned the established threshold concept.

Swets' data showed that observers could be made to establish different levels of a 'criterion' for saying 'yes' to a faint visual signal. Criterion could be manipulated either by establishing different pay amounts for a hit (correct identification of the presence of a signal) and fines for a false alarm (incorrect report of a signal when none was present), or by varying the

chance that a signal would be present on a trial. So, for the same stimulus intensity, observers varied their hit rate along with the false-alarm rate, depending on payoffs or signal likelihood. This behavior was consistent with the Peterson and Birdsall predictions, and with the measure of performance d′ (dee-prime), which was found to be consistent across different criterion settings, representing the distance between the means of assumed underlying distributions.

As an aside, Tanner and Swets adopted Peterson and Birdsall's measure *D*, but as psychologists with training in statistics, they preferred the distance measure, which was the square root of *D*. However, 'square root of *D*' was found to be awkward in conversation and in writing, so they shortened the phrase to d′ and the alternative designation stuck.

A further indication of the notion of a continuum of underlying likelihood in psychophysical tasks was Swets' demonstration that observers could maintain several criteria simultaneously, rating each presentation of a stimulus (or nonstimulus catch-trial) on a numerical scale. If experience were all-or-none, such a task would be impossible. The data from the rating experiment corresponded to the receiver operating characteristic (ROC) presented by Peterson and Birdsall. Rating data could be analyzed to yield pairs of hit and false-alarm rates corresponding to each separate criterion. The theoretical relationship, graphically, was a smooth curve from (0,0) to (1.0,1.0) when hit and false-alarm percentages were plotted against each other. An observer in this task who saw stimuli on an all-or-none basis and sometimes guessed, would yield a straight-line ROC, intercepting the vertical false-alarm axis at the 'guessing' rate; the data were satisfyingly on the side of a Detection Theory curvilinear ROC.

A further demonstration of the continuous nature of a sensory input was from the 'second-choice' experiment. These data were summarized in an influential science article by Swets (1961), from the earlier technical report (Swets et al., 1955). In this experiment, a faint spot of light was flashed on an illuminated background during one of four time intervals. Observers were to indicate their choice and then to indicate which of the remaining three intervals might have contained the signal if they might have been wrong in their initial choice. If a threshold all-or-none mechanism were at play, then on those trials when the first choice was incorrect no information would be available, and the second choice could only have been correct by chance, 33.3%; while if a continuous process underlay the decision, then the second choice should have been right more often than chance, and the theory predicted the percentage of correct second guesses, increasing with flash intensity. The data strongly supported the idea of a continuum of information, as opposed to an all-or-none threshold process.

Propagation and Adaptation

Swets, with a new PhD degree, went to Cambridge, to MIT, where J.C.R. Licklider had become an enthusiastic proponent of the new Detection Theory. Swets has credited Licklider for pushing the editor of the Psychological Review to publish the combined theoretical and empirical Tanner and Swets article. While teaching at MIT, Swets joined the acoustical consulting and research firm Bolt, Beranek and Newman on a part-time basis, a connection which eventually led to full-time involvement and ultimately to the title of Chief Scientist.

Tanner's laboratory was joined by graduate student David M. Green, who as an undergraduate had participated as an observer in the visual experiments. This collaboration led to support for the Detection Theory approach in the auditory detection realm, with an influential technical report by Tanner et al. (1956). It is said that at MIT people around Licklider, hearing him talk so often of this work, thought the author to be a single person, named Tanner Swetsngreen. Green, having completed his PhD, joined Swets at MIT. He subsequently taught at the University of Pennsylvania and at the University of Florida.

Other laboratories followed, with focus on application to other areas of human perception. For instance, James P. Egan, at Indiana University began studies of speech processing (e.g., Egan et al., 1956), which focused on Detection Theory analysis, and Egan published a monograph on uses of ROC analysis (Egan, 1975).

Meanwhile researchers in other psychological research areas saw that the concept of a continuum of evidence was an extraordinarily useful framework. One important area was in the study of verbal memory. For instance the idea of verbal recognition as a problem of extracting signal from noise, basically as a correlation process, was proposed by Murdock (1982), and many researchers came to understand the meaning of false alarms in recognition tasks, using ROC analysis. An excellent summary of much of this work was provided by Benjamin et al. (2009). Creelman (1962) proposed a model for human time discrimination, attempting to identify the nature of the internal timekeeper for comparison of short durations.

At the same time, the medical world was introduced to Detection Theory by Metz (1978). In collaboration with Swets, Metz introduced concepts from Detection Theory, pointing out the necessity to consider false alarms as well as hits in diagnostics. Metz introduced the terms currently used in medicine, 'sensitivity,' the proportion of correct identification of disease processes (hit rate) and 'specificity,' the proportion of correct decisions that disease was not present (1.0 – false-alarm rate). These statistically independent measures have now become standard in the medical literature. Metz introduced the ROC curve to his medical colleagues and explained the equivalence of detectability for all pairs of hits and false alarms along the same ROC. The notion that for the same capability to detect, for instance a breast cancer, the diagnostician could select one criterion level or another and thus achieve more hits, but at the cost of more false alarms, was and remains an important consideration for an X-ray reader. Detection Theory requires sensitivity on the part of the diagnostician to the likelihood of disease and to the costs and benefits of treatment (or of failure to treat) in the case of a positive finding. These are the same issues that Swets explored in his original laboratory studies of masked visual stimuli, and which Green, Birdsall, and Tanner demonstrated in the auditory realm.

The Ideal Observer

In building electronic detection systems, the specification of an ideal level of performance was important, limiting efforts

to achieve better-than-ideal results. One aspect of the work of Peterson and Birdsall was to specify, for any combination of signal and masking noise, a maximum possible detection performance, an ideal observer. The combination of optimal signal-processing procedure and decision strategy established a ceiling on possible performance. Tanner and Birdsall (1958) defined *efficiency* of a receiver (or a human listener) as the ratio of the obtained performance to that of an ideal. Tanner then showed (Tanner, 1961) that various ways of specifying the signal to observers, for instance marking the observation precisely, could improve efficiency. Much later Taylor and Forbes (1969) showed that with sufficient information, presented binaurally, near-ideal detection was possible for their human observers. In study of human detection and animal physiological responses, the ideal approach proved useful (Cohn et al., 1975). This work followed upon the much earlier studies by Kuffler et al. (1956), showing that neural rates of firing in response to light stimuli were not fixed, but random.

Multidimensional Extensions

Tanner introduced the concept that detection could be measured for differences in the magnitude of sensory experience, showing that detection of a difference could be considered simply as a detection problem, where the 'signal' to be detected was the difference between two possible sensory inputs. This work was summarized in the PhD thesis that Tanner finally presented (Tanner, 1960). Later Creelman (1963, 1965) showed that Detection Theory measures along unidimensional sensory continua such as loudness and lengths of lines could be shown to be additive. Tanner (1956) extended the analysis, showing that discrimination between auditory signals of different frequencies could be modeled successfully in two dimensions, where detectability of each signal was plotted along a separate axis, and the listener's ability to distinguish between them was measured as the angle between the axes. These ideas have been greatly extended to analysis of multidimensional stimulus sets in the work of Ashby and Townsend (Ashby, 1992; Ashby and Gott, 1988).

Spreading the Word: Books and Conferences

The definitive presentation of Signal Detection Theory, as a theoretical framework and a way to conduct psychophysical experiments, was published by Green and Swets (1966). A more recent overview of theory and experiment is by Macmillan and Creelman (2005). Swets and Picket (1982) summarized the broader applications of Detection Theory in areas as diverse as medical diagnostics and library item retrieval. Swets (1964, Revised Ed. 1988) reprinted a collection of influential articles showing the extent to the time of applications. Elementary introductions have been published by McNicol (1972) and Wickens (2002). Lively discussion among psychologists working in audition over the years has been at meetings of the Acoustical Society of America.

Some Detractors

Attacks on the conceptualizations that underlie Detection Theory, as it is applied to psychophysics, came from several directions. One line of attack was simply to dismiss it as nothing new, as using the 'time worn concepts of probability theory' to complicate the relatively simple field of psychophysics (Stevens, 1964). A more sophisticated approach has been that of Balakrishnan (1999), and he has recently offered an alternative approach to measure sensory discrimination (Balakrishnan and MacDonald, 2011). Krantz (1969) showed that published ROC curve data might be accounted for with a sophisticated multiple-threshold theory. Another line of discussion has involved attempts to free detection measures from the assumptions underlying calculation of d′, particularly the reliance on the assumption regarding the shape of the underlying distributions, the Gaussian normal distribution. These 'nonparametric' approaches (Pollack and Norman, 1964; Donaldson, 1992) were shown by Macmillan and Creelman (1996) in fact to imply distributional underpinnings consistent with the version of the theory developed by Luce (1959), which used the logistic distribution instead of the Gaussian.

Importance for Psychology

Signal Detection Theory, along with Information Theory (Miller, 1956), was an early harbinger of the cognitive revolution in psychology (Neisser, 1967). With its focus on the processes involved in decision making and signal analysis, processes presumed to be carried out by human and animal perceivers, the approach showed that a model specifying internal, assumed complex cognitive functioning could be explored experimentally.

Abstract

Tests of significance are used in statistics to assess the agreement between data and models. This article describes how such tests are formulated and used, illustrates this with several examples, and discusses some difficulties in interpretation that have been raised.

A test of significance assesses the agreement between the data and a hypothesized statistical model. The magnitude of the agreement is expressed as an observed level of significance, or *p*-value, which is the probability of obtaining data as or more extreme than the observed data, if the hypothesized model were true. A very small *p*-value suggests that either the observed data are not compatible with the hypothesized model or an event of very small probability has been observed. A large *p*-value indicates that the observed data are compatible with the hypothesized model. As the *p*-value is a probability, it must be between 0 and 1, and a very common convention is to declare values smaller than 0.05 as 'small' or 'statistically significant' and values larger than 0.05 as 'not statistically significant.' The historical rationale for this very arbitrary cut-off point is that the calculation of a *p*-value was difficult, and tables useful for common statistical models were prepared for general use.

To make this more concrete, it is necessary to consider statistical models and the notion of a (simplifying) hypothesis within that model. The theory of this is outlined in Section Model-Based Inference, with some more specific points considered in Section Further Topics. Section Difficulties with Significance Tests provides some brief comments on criticisms of significance tests. This introduction concludes with a highly idealized example to convey the idea of data being inconsistent with a hypothesized model.

Example 1. Students in a statistics class partake in an activity to assess their ability to distinguish between two competing brands of cola, and to identify from taste alone their preferred brand. Each of the 20 students expresses a preference for one brand or the other, but just one student claims to be able to discriminate perfectly between the two. Twenty cups of each brand are prepared by the instructor and labeled '1' and '2.' Each student is presented with a pair of cups and asked to record which label corresponds to Brand A. The result is that 12 students correctly identify the competing brands, although the student who claimed a perfect ability to discriminate identified the brands incorrectly.

The labeling of the cups as 1 or 2 by the instructor was completely random, i.e., cup 1 was equally likely to contain Brand *A* or *B*. The students did not discuss their opinions with their classmates, and the taste testing was completed fairly quickly. Under these conditions, it is plausible that each student has a probability of $\frac{1}{2}$ of identifying the brands correctly simply by guessing, so that about 10 students would correctly identify the brands with no discriminatory ability at all. That 12 students did does not seem inconsistent with guess work, and the *p*-value helps to quantify this. The probability of observing 12 or more correct results if one correct result has probability $\frac{1}{2}$ and the guesses are independent can be computed by the binomial formula as $\left\{\binom{20}{12}+\binom{20}{13}+\cdots+\binom{20}{20}\right\}\left(\frac{1}{2}\right)^{20} = 0.34$: there is no evidence from these data that the number of correct answers could not have been obtained by guessing: in more statistical language assuming a binomial model, the observed data is consistent with probability of success $\frac{1}{2}$.

The student who claimed to have perfect discrimination, but actually guessed incorrectly, argued that her abilities should not be dismissed on the basis of one mistake, so the class carried out some computations to see what the *p*-value for the same observed data would be if the number of pairs of cups was increased. The probability of one or zero mistakes in a set of *n* trials for various values of *n*, is given in Table 1. From this we see that, for example, one or no mistakes in five trials is consistent with guess work but the same result in 10 trials is much less so.

In both parts of this example we assumed a model of independent trials, each of which could result in a success or failure, with constant probability of success. Our calculations also assumed this constant probability of success was 0.5. This latter restriction on the model is often called a 'null hypothesis' and the test of significance is a test of this null hypothesis; the *p*-value measures the consistency of the data with this null hypothesis. In many applications the null hypothesis plays the role of a conservative position that the experimenter hopes to disprove, and one reason for requiring rather small *p*-values

Table 1 Probability of zero or one mistakes in *n* independent Bernoulli trials with probability of a mistake = 0.5

n	*Probability*
5	0.1875
6	0.1094
7	0.0625
8	0.0352
9	0.0195
10	0.0107
11	0.0059
12	0.0032
13	0.0017
14	0.0009
15	0.0002

before declaring statistical significance is to raise the standard of proof required to replace a relatively simple working hypothesis by one that is possibly more complex and less well understood.

As formulated here the hypothesis being tested is that the probability of a correct choice is 0.5, and not the other aspects of the model, such as independence of the trials, and unchanging probability of success. The number of observed successes does not measure such model features, it provides information only on the probability of success. Functions of the data that do measure such model features can be constructed, and from these significance tests that assess the fitness of an assumed model; these play an important role in statistical inference as well.

Model-Based Inference

Models and Null Hypothesis

We assume that we have a statistical model for a random variable Y taking values in a sample space $\mathcal{Y}$, described by a parametric family of densities $\{f(y;\theta);\theta\in\Theta\}$. Tests of significance can in fact be constructed in more general settings but this framework is useful for defining the main ideas. If Y is the total number of successes in n independent Bernoulli trials with constant probability of success, then

$$f(y;\theta) = \binom{n}{y}\theta^y(1-\theta)^{n-y} \qquad [1]$$

$\Theta = [0,1]$, and $\mathcal{Y} = \{0,1,\ldots,n\}$. If Y is a continuous random variable following a normal or bell curve distribution with mean θ_1 and variance θ_2^2, then

$$f(y;\theta) = \frac{1}{\sqrt{2\pi}\theta_2}\exp\left\{-\frac{1}{2\theta_2^2}(y-\theta_1)^2\right\} \qquad [2]$$

$\Theta = \mathbb{R}\times\mathbb{R}^+$ (R - real line; R - positive real line), and $\mathcal{Y} = \mathbb{R}$. The model for n independent observations from this distribution is

$$f(y_1,\ldots,y_n;\theta) = \frac{1}{\left(\sqrt{2\pi}\right)^n\theta_2^n}\exp\left\{-\frac{1}{2\theta_2^2}\sum_{i=1}^n(y_i-\theta_1)^2\right\} \qquad [3]$$

$\Theta = \mathbb{R}\times\mathbb{R}^+$, and $\mathcal{Y} = \mathbb{R}^n$. For further discussion of statistical models, *see* Statistical Sufficiency; Distributions, Statistical: Special and Discrete; Distributions, Statistical: Approximations; Statistical: Special and Continuous.

As noted above, we assume the model is given, and our interest is in inference about the parameter θ. While this could take various forms, a test of significance starts with a so-called *null hypothesis* about θ, of the form

$$H_0 : \theta = \theta_0 \qquad [4]$$

or

$$H_0 : \theta\in\Theta_0 \qquad [5]$$

In [4] the parameter θ is fully specified, and H_0 is called a *point* null hypothesis or a *simple* null hypothesis. If θ is not fully specified, as in [5], H_0 is called a *composite* null hypothesis. In the taste-testing examples the simple null hypothesis was $\theta = 0.5$. In the normal model, [2], a hypothesis about the mean, such as $H_0 : \theta_1 = 0$, is composite, as the variance is left unspecified. Another composite null hypothesis is $H_0 : \theta_2 = \theta_1$, which restricts the full parameter space to a one-dimensional curve in $\mathbb{R}\times\mathbb{R}^+$.

A test is constructed by choosing a *test statistic* which is a function of the data that in some natural way measures departure from what is expected under the null hypothesis, and which has been standardized so that its distribution is known either exactly or to a good approximation under the null hypothesis. Test statistics are usually constructed so that large values indicate a discrepancy from the hypothesis.

Example 2. In the binomial model [1], the distribution of Y is completely specified by the null hypothesis $\theta = 0.5$ as

$$f(y) = \binom{n}{y}2^{-n}$$

and consistency of a given observed value y_0 of y, is measured by the p-value $\sum_{y=y_0}^n\binom{n}{y}2^{-n}$, the probability of observing a value as or more extreme than y_0. If y_0 is quite a bit smaller than expected, then it would be more usual to compute the p-value as $\sum_{y=0}^{y_0}\binom{n}{y}2^{-n}$. Each of these calculations was carried out in the discussion of taste testing in the Introduction.

Example 3. In independent sampling from the normal distribution, given at [3], we usually test the composite null hypothesis $H_0 : \theta_1 = \theta_{10}$, by constructing the *t-statistic*

$$T = \sqrt{n}\left(\overline{Y}-\theta_{10}\right)/S$$

where $\overline{Y} = n^{-1}\sum_{i=1}^n Y_i$ and $S^2 = (n-1)^{-1}\sum(Y_i-\overline{Y})^2$. Under H_0, T follows a t-distribution on $n-1$ degrees of freedom, and if large values of T are considered evidence against H_0, the p-value is

$$\Pr\left\{T\geq\sqrt{n}\left(\overline{y}-\theta_{10}\right)/s\right\}$$

where $\overline{y}$ and s are the values observed in the sample. (If small values of T are considered evidence against H_0, we would use the other tail of the distribution; see Section Two-Sided Testing for comments on two-sided tests of significance.) This probability needs to be computed numerically from an expression for the cumulative distribution function of the t-distribution. Historically tables of this distribution were provided for ready reference, typically by identifying a few critical values, such as $t_{0.10}$, $t_{0.05}$, and $t_{0.01}$ satisfying $\Pr\{T_\nu\geq t_\alpha\} = \alpha$, where T_ν is a random variable following a t-distribution on ν degrees of freedom. It was arguably the publication of these tables that led to a focus on the use of particular fixed levels for testing in applied work.

Example 4. Assume the model specifies that $Y_1,\ldots,Y_n$ are independent, identically distributed from a distribution with density $f(\cdot)$ on $\mathbb{R}$ and that we are interested in testing whether or not $f(\cdot)$ is a normal density:

$$H_0 : f(y) = \left(\sqrt{2\pi}\right)^{-1}e^{-\frac{1}{2}y^2} \qquad [6]$$

or

$$H_0 : f(y) = \left(\sqrt{2\pi}\right)^{-1}\theta_2^{-1}\exp\left\{-(y-\theta_1)^2/\left(2\theta_2^2\right)\right\} \qquad [7]$$

the former is a simple and the latter is a composite null hypothesis. For this problem it is less obvious how to construct

a test statistic or how to choose among alternative test statistics. Under [6] we know the distribution of each observation (standard normal) and thus of any function of the observations. The ordered values of Y could be compared to their expected values under [6], for example by plotting one against the other, and deviation of this plot from a line with intercept 0 and slope 1 could be measured in various ways. In the case of the composite null hypothesis [7], we could make use of the result that under H_0, $(Y_i - \overline{Y})/S$ has a distribution free of θ_1 and θ_2, and the vector of these residuals is independent of the pair $(\overline{Y}, S^2)$, and then for example compare the sample skewness $n^{-1}\sum_{i=1}^{n}\{(Y_i - \overline{Y})/S\}^3$ with that expected under normality.

Example 5. Suppose we have a sample of independent observations $Y_1,\ldots,Y_n$ on a circle of radius 1 and our null hypothesis is that the observations are uniformly distributed on the circle. One choice of a test statistic is $T_1 = \sum_{i=1}^{n}\cos(Y_i)$, very large positive (or negative) values indicating a concentration of observations at angle 0 (or π). If we instead wish to detect clumps of observations at two angles differing by π then $T_2 = \sum_{i=1}^{n}\{\cos(2Y_i) - 1\}$ would be more appropriate. The exact distribution of T_1 under H_0 is not available in closed form, but the mean and variance are readily computed as 0 and n, so a normal approximation might be used to compute the p-value.

In the examples described above the test statistics are ad hoc choices likely to be large if the null hypothesis is not true; these are called pure tests of significance, and are treated in detail in Cox and Hinkley (1974: Chapter 3); Examples 4 and 5 above are drawn from that chapter. A more sensitive test can be constructed if we have more specific knowledge of the likely form of departures from the null hypothesis. The theory of hypothesis testing formalizes this by setting up a null hypothesis and alternative hypothesis, and seeking to construct an optimal test for discriminating between them (*see* Hypothesis Testing, in Statistics). In the remainder of this section we consider an approach based on the likelihood function.

Significance Tests Based on Likelihood

In parametric models tests of significance are often constructed by using the likelihood function, and the p-value is computed by using an established approximation to the distribution of the test statistic. The likelihood function is proportional to the joint density of the data:

$$L(\theta; y) = c(y)f(y; \theta) \qquad [8]$$

see Likelihood, Methods of Statistical Inference.

We first suppose that we are testing the simple null hypothesis $H_0 : \theta = \theta_0$ in the parametric model $f(y; \theta)$. Three test statistics often constructed from the likelihood function are the Wald or maximum likelihood statistic:

$$w_e = \left(\widehat{\theta} - \theta_0\right)^T j\left(\widehat{\theta}\right)\left(\widehat{\theta} - \theta_0\right) \qquad [9]$$

the Rao or score statistic:

$$w_u = U(\theta_0)^T\left\{j\left(\widehat{\theta}\right)\right\}^{-1}U(\theta_0) \qquad [10]$$

and the likelihood ratio statistic:

$$w = 2\left\{\ell\left(\widehat{\theta}\right) - \ell(\theta_0)\right\} \qquad [11]$$

where in [8], [9], and [10] the following notation is used:

$$\sup_{\theta} L(\theta; y) = L\left(\widehat{\theta}; y\right) \qquad [12]$$

$$\begin{aligned} \ell(\theta) &= \log L(\theta) \\ U(\theta) &= \ell'(\theta) \end{aligned} \qquad [13]$$

$$j(\theta) = -\ell''(\theta) \qquad [14]$$

The distributions of each of the statistics [8], [9], and [10] can be approximated by a χ^2_k distribution, under the model $f(y; \theta_0)$, with k the dimension of θ in the model. This relies on being able to apply a central limit theorem to $U(\theta)$, and to identifying the maximum likelihood estimator $\widehat{\theta}$ with the root of the equation $U(\theta) = 0$. The precise regularity conditions needed are somewhat elaborate; see for example Lehmann and Casella (1998: Chapter 6) and references therein. The important point is that under the simple null hypothesis the approximate distributions of each of these test statistics is known, and p-values readily computed.

In the case that the hypothesis is composite, a similar triple of test statistics computed from the likelihood function is available, but the notation needed to define them is more elaborate. The details can be found for example in Cox and Hinkley (1974: Chapter 9.3) and the notation above follows theirs.

If θ is a one-dimensional parameter, then a one-sided version of the test statistics given at [8], [9], and [10] can be used instead, as the signed square root of w_e, w_u, or w follows approximately a standard normal distribution.

It is rare that the exact distribution of test statistics can be computed, but the normal or chi-squared approximation can often be improved. These improvements are discussed in Barndorff-Nielsen and Cox (1994), Pace and Salvan (1997), Severini (2000) and Brazzale et al. (2007). One conclusion of this work is that among the three test statistics above, the signed square root of the likelihood ratio statistic w is generally preferred on a number of grounds, including the accuracy of the normal approximation to its exact distribution. This is true for both simple and composite tests of a scalar parameter.

Significance Functions and Posterior Probabilities

We can also use a test of significance to consider the whole set or interval of values of θ that are consistent with the data. If θ is scalar one of the simplest ways to do this is to compute $r(\theta) = \pm\sqrt{w(\theta)}$ as a function of θ, and tabulate or plot $\Phi\{r(\theta)\}$ against θ, choosing the negative root for $\widehat{\theta} < \theta$, and the positive square root otherwise. This significance function will in regular models decrease from one to zero as θ ranges over an interval of values. The θ values for which $\Phi(r)$ is 0.975 and 0.025 provide the endpoints of an approximate 95% confidence interval for θ. This approach is emphasized in Fraser (1991).

In a Bayesian approach to inference it is possible to make probability statements about the parameter or parameters in the model by constructing a posterior probability distribution for them. In a model with a scalar parameter θ based on a prior $\pi(\theta)$ and model $f(y; \theta)$ we compute a posterior density for θ as

$$\pi(\theta|y) \propto f(y; \theta)\pi(\theta) \qquad [15]$$

and can assess any particular value θ_0 by computing

$$\int_{\theta_0}^{\infty} \pi(\theta|y)d\theta$$

the posterior probability of θ being larger than θ_0. This posterior probability is different from a p-value: a p-value assesses the data in light of a fixed value of θ, and the posterior probability assesses a fixed value of θ in light of the probability distribution ascribed to the parameter. Many people find a posterior probability easier to understand, and indeed often interpret the p-value in this way. There is a literature on choosing priors called 'matching priors' to reconcile these two approaches to inference; see Kass and Wasserman (1996), and Datta and Mukerjee (2004); see also Bayesian Statistics. Unfortunately it is not possible to find so-called matching priors that are simultaneously matching for all components of a vector parameter.

Hypothesis Testing

Little has been said here about the choice of a test statistic for carrying out a test of significance. The difficulty is that the theory of significance testing provides no guidance on this choice. The likelihood-based test statistics described above have proved to be reasonably effective in parametric models, but in a more complicated problem, such as testing the goodness of fit of a hypothesized model, this approach is often not available. To make further progress in the choice of test statistics, the classical approach is to formulate a notion of a 'powerful' test statistic, i.e., one that will reliably give small p-values when the null hypothesis is not correct. To do this in a systematic way requires specifying what model might hold if in fact the null hypothesis is incorrect. In parametric models where the null hypothesis is $H_0 : \theta = \theta_0$ the alternative may well be $H_a : \theta \neq \theta_0$. In more general settings the null hypothesis might be H_0 : 'the response variable follows a normal distribution' and the alternative H_a : 'the response variable does not follow a normal distribution.' Even in the parametric setting if θ is a vector parameter it may be necessary to consider what direction in the parameter space away from θ_0 is of interest. The formalization of these ideas is the theory of hypothesis testing, which considers both null and alternative hypotheses and optimal choices of test statistics (*see* Hypothesis Testing, in Statistics; Goodness of Fit: Overview; Methods and Models).

Further Topics

Fixed Level Testing

The problem of focusing on one or two so-called critical p-values is sometimes referred to as fixed-level testing. This was useful when computation of p-values was a very lengthy exercise, and it was usual to provide tables of critical values. It is now usually a very routine matter to compute the exact p-value, which is usually (and should be) reported along with other details such as sample size, estimated effect size, and details of the study design. There is still in some quarters a reliance on fixed level test, with the result that studies for which the p-value is judged 'not statistically significant' may not be published. This is sometimes called the 'file drawer problem,' and a quantitative analysis was considered in Dawid and Dickey (1977).

In several fields it is now standard to make the results of all studies on a given topic, including inconclusive studies, available online. In healthcare the Cochrane collaboration is perhaps the best-known of these. This issue is particularly important for *meta-analysis*, see Section Combining Tests of Significance.

Achievable *p*-values

In some problems where the distribution of the test statistic under the null hypothesis is concentrated on a discrete set, the number of available p-values will be relatively small. This happens with categorical data, especially if the sample size is small. Some authors have argued that for such highly discrete situations a better assessment of the null hypothesis can be achieved by the use of Barnard's mid p-value, which replaces $\Pr\{t(Y) \geq t^0\}$ with $(1/2)\Pr\{t(Y) = t^0\} + \Pr\{t(y) > t^0\}$, where $t(Y)$ is the statistic on which the significance test is based, and t^0 is the observed value in the data; see Agresti (1992) and references therein.

Combining Tests of Significance

The p-value is a function of the data, taking small values when the data are incompatible with the null hypothesis, and vice versa. As a function of y the p-value itself has a distribution under the model $f(y;\ \theta)$ and in particular under the null hypothesis H_0 has the uniform distribution on the interval $(0,1)$. In principle then if we have computed p-values from a number of different datasets the p-values can be compared to observations from a $U(0,1)$ distribution with the objective of obtaining evidence of failure of the null hypothesis across the collection of datasets. This is one of the ideas behind *meta-analysis*; *see* Meta-analysis: Overview; Meta Analysis: Tools. One difficulty is that the studies will nearly always differ in a number of respects that may mean they are not all measuring the same parameter, or measuring it in the same way. Another difficulty is that studies for which the p-value is not 'statistically significant' will not have been published, and thus are unavailable to be included in a *meta-analysis*. This selection effect may seriously bias the results of the *metametaanalysis*. In some fields this selection effect has been lessened by the practice of registering all trials in a given subject area on the internet.

Two-Sided Testing

A point of confusion in the evaluation of p-values for testing scalar parameters is the distinction sometimes made between one-sided and two-sided tests of significance. A reliable procedure is to compute the p-value as the twice the smaller of the probabilities that the test statistic is larger than or smaller than the observed value, under the null hypothesis. This so-called two-sided p-value measures disagreement with the null hypothesis in two directions away from the null hypothesis, toward the alternative that the, say, new treatment is worse than the old treatment as well as better. In the absence of very

concrete a priori evidence that the alternative hypothesis is genuinely one-sided this *p*-value is preferable.

In testing hypotheses about parameters of dimension larger than one, it can be difficult to decide on the relevant direction away from the null hypothesis. One solution is to identify the parameters of interest individually, and carry out separate tests on each of these parameters in turn. This will usually be effective if there are a relatively small number of parameters of interest. In applications involving computation of a very large number of *p*-values, new techniques are needed; these are briefly discussed in the next section.

Difficulties with Significance Tests

Sample Size

In Figure 1 we show the *p*-value for a one-sided *t*-test with an observed value of the *t*-statistic equal to 2.0, as a function of the sample size. In this example, and quite generally, the *p*-value is a decreasing function of the size of the sample, so that a very large study is more likely to show 'statistical significance' than a smaller study. This has led to considerable criticism of the *p*-value as a summary measure. The *p*-value is also sometimes misinterpreted, especially when it is small, as the probability that the null hypothesis is false. Some statisticians have argued that for this reason posterior probabilities are a better measure of disagreement with the null hypothesis; see for example Berger and Sellke (1987) and Schervish (1996).

To some extent the criticism can be countered by noting that the *p*-value is just one summary measure of a set of data, and excessive reliance on one measure is inappropriate. In a parametric setting it is nearly always advisable to provide, along with the *p*-value for testing a particular value of the parameter of interest, an estimate of the effect size, or some relevant parameter of the model, along with an indication of the precision of this estimate. This can be accomplished by reporting a significance function, if the parameter of interest is one-dimensional. At a more practical level, it should always be noted that a small *p*-value should be interpreted in the context of other aspects of the study. For example a *p*-value of less than 0.05 could be based on a very small difference in a study of 10 000 cases or a relatively large difference in a study of 1000 cases. A 1% reduction in an average response may be of substantial importance for one scientific context, and meaningless for others; this needs to be evaluated in that context, and not by relying on the fact that it is 'statistically significant.' Unfortunately, the notion that a study report is complete if and only if the *p*-value is found to be less than 0.05 is fairly widely ingrained in some disciplines, and indeed forms a part of the requirements of some government agencies for approving new treatments.

Figure 1 The *p*-value associated with an observed *t*-statistic equal to 2.0, as a function of the sample size.

Multiple Testing

If a number of significance tests are carried out on the same set of data, but the significance level, or *p*-value, that is reported is the smallest of these, then a different analysis is needed. This smallest *p*-value will not have the interpretation of a *p*-value from a single test; for example if we regard *p*-values less that 0.05 as 'significant,' then we would expect to find 5 spuriously significant results in 100 tests, on average.

In some applications there might be two or three thousand tests carried out, all of a similar type. One example arises in image analysis, for example comparing the blood flow in each of several thousand pixels or voxels of a brain scan, under two (or more) conditions. Large numbers of *t*-tests are often conducted in genomic analysis of expression arrays, with again the goal of comparing two conditions. The *p*-value for a single such comparison is no longer a reliable measure of the consistency of the data with the null hypothesis; several *p*-values will be small even when the null hypothesis is true, simply by chance.

There is a large literature on assessments of hypotheses under multiple testing, that has become particularly prominent in biological applications, but also has applications to many other sciences. *See* False Discovery Rate; Multiple Comparisons A good statistical theory reference is Efron (2010), and there are a number of more specialized books, for particular scientific fields, such as Dudoit and van der Laan (2008). In high-energy physics the search for new particles involves looking through a great many energy bands, sometimes called in that context the 'look elsewhere' effect, and it has become conventional to require a so-called '5-sigma' result to claim discovery of a new particle. This relates the observed level of significance to the probability that a normal random variable exceeds its mean by five standard deviations; this probability is 3×10^{-7}.

In many areas of research the delineation of the number of significance tests that have been carried out, but are not reported, is less clear. For example, in a new epidemiological study of the health effects of some environmental agent, several different models may be fitted to the data, including perhaps various transformations of the exposure measurements, different levels of control for confounding, and so on. Again the evidence provided by any single reported significance test needs to be considered in the light of the many other

tests that may have been formally or informally applied to the same data.

The reliance on multiple significance tests forms a part of the increasing concern, in the academic and in the popular press, about the replicability of published scientific research; see for example, Ioannidis (2005), or Economist (2013). Research in this area is ongoing; for a recent discussion in the medical context see Jager and Leek (2013) and the accompanying discussion.

Conclusion

A test of statistical significance is a mathematical calculation based on a test statistic, a null hypothesis, and the distribution of the test statistic under the null hypothesis. The result of the test is to indicate whether the data are consistent with the null hypothesis: if they are not, then either we have observed an event of low probability, or the null hypothesis is not correct.

The choice of test statistic is in principle arbitrary, but in practice might be determined by convention in the field of application, by intuition in a relatively new setting, or by one or more considerations developed in statistical theory. It is convenient to use test statistics whose distributions can be easily calculated exactly or to a good approximation. It is useful to use a test statistic that is sensitive to the particular departures from the null hypothesis that are of particular interest in the application.

A test of statistical significance is just one component of the analysis of a set of data, and should be supplemented by estimates of effects of interest, considerations related to sample size, and a discussion of the validity of any assumptions of independence or underlying models that have been made in the analysis. A statistically significant result is not necessarily an important result in any particular analysis, but needs to be considered in the context of research in that field.

An eloquent introduction to tests of significance is given in Fisher (1935: Chapter II). Kalbfleisch (1979: Chapter 12) is a good text book reference at an undergraduate level. The discussion here draw considerably from Cox and Hinkley (1974: Chapter 3), which is a good reference at a more advanced level. An excellent overview is given in Cox (1977).

Abstract

This article presents a general overview of the life and thoughts of Georg Simmel from the perspective of the social sciences. After a brief biographical introduction, a discussion of those aspects of his *oeuvre*, which enjoy close proximity with the social sciences, particularly sociology, will constitute the main focus of the article. Together with Max Weber and Emile Durkheim, Simmel is one of the great classical theorists of sociology, and, as will be shown herein, contributed substantially to the development of the discipline, freeing it from needing to be an all-encompassing study of society as a whole. Thus, an overview of Simmel's fundamental theoretical concepts will be delivered, with the aim of illustrating his central relevance to the field of the social sciences.

Georg Simmel: A Biographical Sketch

Georg Simmel was born in the heart of Berlin on 1 March 1858. He was the youngest son of Flora (born Bodstein) and Eduard Simmel, who, although coming from Jewish families, had been baptized into Christianity (he as a Catholic, she as a Protestant). Following the early death of Simmel's father in 1874, the family suffered serious financial difficulties, which, as far as the young Georg was concerned, were overcome thanks to Julius Friedländer, a friend of the family (cofounder of the music publishing company 'Peters'). Friedländer felt a strong sympathy for the young Simmel, and indeed took him under his wings as his protégé. Thus, Georg could attend high school and then university in Berlin, where he studied philosophy, history, art history, and social psychology (*Völkerpsychologie*). Simmel received his degree as Doctor of Philosophy in 1881, but not without difficulty: his first attempt at a doctoral thesis, *Psychological and Ethnological Studies on the Origins of Music*, was not accepted, and he had instead to submit his previous work on Kant, *On the Essence of Matter – Das Wesen der Materie nach Kant's Physischer Monadologie*, which had earned him a prize (Köhnke, 1996). The *Habilitation* (postdoctoral qualification to lecture) came next in 1885, for which he also encountered some controversy, and after this his academic career began immediately as a *Privatdozent* (external lecturer). An extraordinary (*außerordentliche*) professorship without salary followed in 1901, and indeed he had to wait until 1914 before he was offered a regular professorship at the University of Strasbourg, where he remained until his death on 26 September 1918, shortly before the end of the First World War.

During his lifetime, Simmel was a well-known figure in Berlin's cultural world. He did not restrict himself merely to scientific or academic matters, but consistently showed great interest in the politics of his time, including contemporary social problems, and in the world of arts. He sought to be in the presence of, and in contact with, the intellectuals and artists of his day. He married the painter Gertrud Kinel, with whom he had a son, Hans, and maintained friendships with Rainer Maria Rilke, Stefan George, and Auguste Rodin, amongst many others. At his home in Berlin, he organized private meetings and seminars (Simmel's *privatissimo*), whose participants he would choose personally.

Georg Simmel and the Social Sciences

Simmel's contributions to the social sciences are immeasurable. Indeed, together with Max Weber (1864–1920) and Émile Durkheim (1858–1917), he set the foundations of that which today is understood as sociology and as the social sciences in general.

Simmel's interest in the social sciences, especially in sociology, can be traced to the very beginning of his academic career. After attending seminars offered by Moritz Lazarus and Heymann Steinthal (founders of the *Völkerpsychologie* (social psychology)) during his student years, he became a member of Gustav Schmoller's circle, where he became acquainted with the debates concerning the national economy of the time, and for whom he held a conference on *The Psychology of Money* (GSG2 1989, pp. 49–65), which would later constitute the first pillar of one of his major works, *The Philosophy of Money* (Simmel, 1989a). In both of these circles Simmel became more aware of, and sensitized toward, social questions. Schmoller's engagement with social questions, together with Lazarus' and Steinthal's emphasis on the level of *'Überindividualität'* (supraindividuality), and their relativistic worldview and insistence that ethical principles are not of universal validity, as well as Simmel's own interest in Spencer's social theory, all helped to shape the contours of his sociological approach. These various influences were melded together with Simmel's philosophical orientation, particularly his interest in Kant, which yielded a new and rather far-reaching sociological perspective that would evolve extensively throughout his life, being merged, at the end of it, with his increasing interest for the philosophy of life.

Simmel's first sociological work, *On Social Differentiation* (*Über Sociale Differenzierung*: Simmel, 1989c), written at the very beginning of his academic career, was deeply influenced by Herbert Spencer and the ideas of Gustav Schmoller and his circle. Slowly, however, as the 1890s drew on, the admiration Simmel had felt for Spencer's theories turned into rejection,

and he distanced himself from an evolutionary-organicist approach to sociology. In this rejection of such theories, he brought his knowledge of Kant to his sociological thinking, and this would become the basis of his later contact and dialog with the members of the southern-German neo-Kantian school, such as Rickert, Windelband, and with the sociologist who was closest to their ideas: Max Weber. This contact with neo-Kantianism influenced Simmel's approach to the social sciences at the end of the nineteenth century and during the initial years of the 1900s. However he did not become a neo-Kantian, and his interpretation and use of Kant's works in his academic work differed from the tendencies that the neo-Kantians shared.

From contemporary testimonies we know that Simmel was in fact one of the greatest lecturers at the University of Berlin, that his seminars were attended by a great number of students, and that his books were widely read and discussed (Gassen and Landmann, 1993). It is thus difficult to understand why Simmel did not have a more successful academic career. We know from his correspondences and from Gassen and Landmann's attempts to reconstruct Simmel's life and *oeuvre* that Georg Jellinek engaged himself, though with no positive results, in seeking to obtain an ordinary professorship for Simmel at the University of Heidelberg in 1908 (with, following Jellinek's death, a further attempt by Alfred Weber in 1912, and another in 1915). His converted Jewish background (and thus, despite of being German, being pointed at with the label of 'Jewishness') surely played a significant role in the lack of recognition Simmel received from the academic system. However, this was not the only cause for his somehow peculiar academic career. His peculiar and original understanding of science, which diverged greatly from established patterns, as well as his characteristic mode of writing, using essays instead of more 'academic' and standardized forms, contributed to his not being accepted into the rather formal and classical German academic milieu. Both attempts at obtaining a professorship for Simmel were blocked by the bureaucracy of the Grand Dukedom of Baden. In fact the letter of evaluation written by the Berlin historian Schäfer regarding a possible professorship for Simmel in Heidelberg in 1908 has as the primary argument for denying Simmel's potential ability to be a good professor his 'Jewishness,' which, according to Schäfer, too obviously tinged Simmel's character and intellectual efforts with a strong relativism and negativity, which could not be good for any student (Gassen and Landmann, 1993; Köhnke, 1996).

Throughout his life Simmel had to fight against these kinds of accusation, which also came from the more conservative neo-Kantian schools of thought; and he endeavored to build a 'positive relativism' in an attempt to show that he did not question 'absolute pillars' and thus leave us with nothing, but sought instead to show that this sense of 'absoluteness' was also a product of human reciprocal actions and effects (*Wechselwirkungen*), and was not fundamentally absolute. As the planets are not held by any strong hand, but by an equilibrium of forces, and notwithstanding the fact that they cannot fall just like that but are firmly held at their place by that very same equilibrium of forces, so do the values which we strongly believe in, the moral constructions or aesthetic evaluations: they are held by the invisible, and yet, so strong, relational threads that keep them at their place. Such an argument was too much for the society and scientific milieu of the time to accept and forgive, even when Simmel later radically rejected his *Introduction to the Moral Sciences* (*Einleitung in die Moralwissenschaft*: Simmel, 1989b; Simmel, 1991), referring to it as a sin of his youth. This was the work in which his relativism, in the critical, 'negative' sense, had been most fully in bloom (Köhnke, 1996).

Simmel's interest in the social sciences and in the positive relativism (which we nowadays tend to call as 'relationism') accompanied him throughout his life. Actually, despite the fact that Simmel shifted his attention during his career from the central concept of society, toward culture first, and life at the end, his interest for 'society,' 'culture,' and 'life' was present with different intensities all the way through his academic writing. Thus, we cannot be surprised that Simmel, in his letter to Célestin Bouglé of 2 March 1908, wrote: "At the moment I am occupied with printing my *Sociology*, which has finally come to its end," and, sentences later, added that work on this book 'had dragged on for fifteen years' (Simmel Archive at the University of Bielefeld); thus indicating that his engagement with sociology was a long-term project. Considering that *Sociology* (*Sociologie*) was first published in 1908 (and therefore his work on it must have begun around 1893), we can find its first seed in his article *The Problem of Sociology* (*Das Problem der Sociologie*) originally published in 1894.

Simmel must have thought this article to be a significant contribution to sociology, in as much as he endeavored to spread it abroad as much as possible. Hence, the French translation of *The Problem of Sociology* appeared, simultaneously with the original German version, in September 1894. The American translation appeared in the *Annals of the American Academy of Political and Social Science* a year later, and, by the end of the century, the Italian and Russian translations were also in print. The American translation is of particular significance, in as much as Simmel emphasized therein, in a footnote, that sociology involved empirical research, and should not be thought of as an independent offshoot from philosophy, but as a science concerning the social problems of his time. In the Italian translation he delivered an updated version of the text, wherein he introduced clear references to his theoretical polemic with Emile Durkheim.

From his letter to Célestin Bouglé of 15 February 1894, we know that Simmel was, after the completion of *The Problem of Sociology*, quite excited by this new discipline, and that he did not foresee a shift away to any other fields of inquiry in his immediate future. During those years he worked on most of the key sociological areas of research, thus articulating the key social problems of his time within a sociological framework: for example, workers' and women's movements, religion, the family, prostitution, medicine, and ethics, amongst many others. He seemed deeply interested in putting his new theoretical proposals and framework for the constitution of sociology into practice. He realized that the institutionalization of the new discipline would be reinforced by the establishment of journals for the discipline; hence his participation in the *Institut Internationale de Sociologie*, for whom he became vice-president; the *American Journal of Sociology*, and, although only briefly (due to differences with Emile Durkheim), *l'Année sociologique* (Rammstedt, 1992: 4). He also played with the idea of creating his own sociological magazine. Another means of solidifying

the role of sociology within the scientific sphere was through the academia, and he engaged himself in organizing sociological seminars, offering them uninterruptedly from 1893 until his death in 1918. On 15 June 1898, he wrote to Jellinek: "I am absolutely convinced that the problem, which I have presented in the *Sociology*, opens a new and important field of knowledge, and the teaching of the forms of sociation as such, in abstraction from their contents, truly represents a promising synthesis, a fruitful and immense task and understanding" (Simmel Archive at the University of Bielefeld). (The collection of all the letters from and to Simmel, which have been found up to date and are available in the Georg Simmel Archive, have been published in the mean time as Simmel (2008a,b).)

It is clear, however, that Simmel did not work continuously on the *Sociology* for 15 years as, from 1897 to 1900, he worked almost exclusively on *The Philosophy of Money* (*Philosophie des Geldes*), and also found time for the writing and publication of his *Kant* (1904), as well as a reprint of his *Introduction to the Moral Sciences* (1904), which he had intended to rewrite, for he no longer accepted most of the ideas he had presented therein when it was first published in 1892 (although he did not achieve this); the revised edition of *The Problems of the Philosophy of History* (*Probleme der Geschichtsphilosophie* 1905), *The Philosophy of Fashion* (*Philosophie der Mode* 1905), and *Religion* (*Die Religion* 1906/1912) were all worked on by Simmel during this period too (Rammstedt, 1992).

In *The Problem of Sociology*, he questioned for the first time the lack of a theoretically well-defined object of study for the emerging discipline, and sought to develop a specific sociological approach, which would entail a distinct object of study, in order to bestow legitimacy and scientific concreteness to a discipline, under attack from different, and more settled, lines of fire. Fearing his call had not been heard, Simmel endeavored to prove his point by writing a broader work, within which he attempted to put into practice the main guidelines he had suggested as being central to the newly emerging discipline. In this way the monograph *Sociology*, almost 1000 pages long, was cobbled together from various bits and pieces, taken from several essays he had written between the publication of *The Problem of Sociology* in 1894 and its final completion in 1908. Simmel, as can be understood from his letters, was aware of the incompleteness of this work, but rescued it by saying that it was an attempt to realize that which he had suggested almost 15 years earlier, for it had not been noticed enough by the scientific community.

By that time (1908), Simmel did not wish to be thought of as only a sociologist. This was due to sociology not being an established discipline within the academic world, which therefore did not allow him to obtain a professorship in the field (i.e., offering very little recognition). Nevertheless he never quite abandoned the field of sociology and continued to write about religion, women's issues, and the family. He merely broadened his scope to include aesthetics, culture, and *Lebensphilosophie* (the philosophy of life), whilst participating at the same time in the founding of the German Sociological Society (*Deutsche Gesellschaft für Soziologie*), for whom he served as one of the chairmen until 1913.

The writing of *Sociology* marks the end of Simmel's strongly Kantian period, and represents a turning point in his interests. From this moment onward, he refused to be merely labeled as a sociologist, seeking instead to return to philosophy. Indeed, following the publication of *Sociology*, he did not publish any sociological articles for 9 years (although he continued, as has already been mentioned, to offer sociological seminars until his death), instead devoting his efforts to philosophy, history, and the philosophy of art. Hence, as part of Simmel's output from these years we find, amongst other works, *Kant und Goethe* (*Kant und Goethe* 1906/1916), *Goethe* (1913), *Kant* (1904/1913/1918), *The Principal Problems of Philosophy* (*Hauptprobleme der Philosophie* 1911), *The Philosophical Culture* (*Philosophische Kultur* 1911/1918), and *Rembrandt* (1916). This new direction was accompanied and partly motivated by Simmel's acknowledgment of Henri Bergson's *oeuvre*, and his inclination toward *Lebensphilosophie* (the philosophy of life; see Fitzi, 1999; Simmel, 1999a). Thus, 'culture' and, later on, 'life' became the primary focus of Simmel's theoretical work, and consequently 'society' was pushed into a secondary role (without ever totally disappearing).

During these years Simmel occupied himself with the study of artists, of their production, and how the relation between life and its formal expression is crystallized in their work. It was as if Simmel had lost interest in sociology, as he did not write a single line concerning it for years. Yet, unexpectedly in 1917, a year before his death, he wrote *Grundfragen der Soziologie* (*The Fundamental Questions of Sociology*). The impetus for writing this book came from a publisher (*Sammlung Göschen*), who intended to print an introductory work to sociology, and which he invited Simmel to write, because of the success other works of his had enjoyed for the same publisher. If Simmel had indeed distanced himself from all sociological questions, it is likely he would have merely reached for the shelf to his previous works and rewritten them in shorter form. But this was not the case, because, although he utilized older material, Simmel rewrote and redefined his perspective, and in *The Fundamental Questions of Sociology*, scarcely 100 pages long, presented the final stage of his sociological reflections, which melded together his previous study of forms of sociation with a perspective from the philosophy of life. This approach to sociology fell into neglect after his death, awaiting revitalization, harboring a broad scope, and original perspective for new generations of sociologists to rediscover. Simmel's last work (1918) was a philosophical contribution to the philosophy of life (*Lebensphilosophie*), the *Lebensanschauung – View of Life* (Simmel, 1999a).

The Object of Sociology

At a time when sociology was still far from being an established discipline, instead seeking to stand up and open its eyes for the first time, Simmel sought to release it from the burden of being 'the science of society.' According to him this burden was an impossible one for the newborn discipline to carry, in as much as being the science of society meant having to compete with already settled and established disciplines for the legitimacy of its object of study: law and history, psychology, and ethnology, all could argue the case that society was their object, thus leaving sociology with the mere pretense of including elements from them all.

Viewed from this perspective, as an object, society was an all-encompassing matter but, at the same time, it eluded any scientific investigation, just like sand falling through our fingers. Simmel contributed to the demystification of 'society' as some kind of essential entity (as it appeared in nineteenth-century sociology, and remained as such in the sociology of Durkheim and Tönnies), instead explaining it as a dynamic process, a continuous happening, a continuous becoming, which is nothing more than the mere sum of the existing forms of sociation.

Individuals as well as society/ies are not units in and of themselves, though they may appear as self-sufficient units depending on the distance the observer interposes between him-/herself and them (as observed objects). However, Simmel argued in *The Fundamental Questions of Sociology* (Simmel, 1999a: 62–68) that if we merely take individuals and pretend, through adopting a significant distance, to approach 'society,' or a social phenomenon, we will not reach our goal. Therefore, when conducting a sociological inquiry, what we must seek to do is base ourselves on the forms of sociation, which are built in *Wechselwirkung*. Simmel used this concept when either addressing 'interactions' or following the Kantian definition as 'reciprocal actions and effects' (Simmel, 1978). The difference between the two possible meanings of this concept, or, more precisely, the differentiation of the two different concepts hidden behind the same word, has been addressed in the English translation of *The Philosophy of Money*; so the usual mistake of translating *Wechselwirkung* as a direct synonym for interaction has been corrected.

According to Simmel, what actually takes place between individuals will be seen to be that which constitutes the object of sociology, not merely the individuals by themselves, or society as a whole, for, as previously mentioned, society is nothing but the sum of forms of sociation, a continuous process in and for which these forms intertwine and combine themselves to form the whole (Simmel, 1992a: 19). Thus, Simmel defined society as the sum of the forms of sociation which emerge and crystallize in *Wechselwirkung*, i.e., in reciprocal actions and effects.

The Concept of 'Form'

If we take reciprocal actions and effects as our starting point, we achieve only a perspective common to all social and human sciences: sociology as method. In order to construct sociology as an independent discipline, with a specific object of study, it is necessary to analytically differentiate between form and content, that is, 'forms' as means and patterns of interaction between individuals, social groups or institutions, and 'contents' as the concrete practices that are embedded within, and channeled by, forms. Thus, social forms were conceived as being the object of analysis for a scientific sociology, which would only be possible empirically. Contents, on the other hand, should be left to other disciplines, such as psychology or history, to analyze.

Simmel's sociological theory is orientated toward these 'forms of sociation' (concept which he included in the writing of *Sociology*). For individuals to become social, they need to rely on such forms in order to channel their contents, as forms represent their only means of participation in social interaction. Forms are independent from contents, and when analyzing them, it is necessary that they are abstracted from individual, particular participation in concrete interactions: the question of social forms does not include that regarding the specific relationships between the participants involved in concrete interactions; we are dealing only with that which is *between* them, as for an analysis of social forms the particular individuals involved in them are irrelevant. Human beings, with their particular 'contents,' are socialized human beings who have learned to realize and express these contents within a social framework: via 'exteriorizing,' via acting through forms. Hence forms are social objectivations, which impose themselves, with their norms, upon particular individuals, an imposition which could only be annulled by isolation. These impositions and constraints are part of what sociation (and socialization) is a concept which plays a key role in Simmel's theory, for he actually maintained that human beings are not social beings by nature, or, at least, asked us not to take this sociability for granted.

Simmel placed the study of the forms of sociation, as a product of reciprocal actions and effects, at the center of his formal, or pure (*reine*), sociology. The form of competition can be used as an example of what Simmel actually meant by 'forms.' Competition does not imply any specific contents, but a set of 'rules of the game' so to speak that remain the same, independent of those who are competing, or what they are competing for. Competition forms 'contents' (such as job seeking, or looking for the attention of a beloved person, amongst many others), limits the boundaries of actions, and actually brings them into being via giving them a framework and shape in which they can appear, be understood and given an appropriate reply to, in the arena of actions and effects.

This situation of having the choice between multiple forms for channeling one content is stressed appreciatively in Simmel's sociology, particularly in his *Lebensphilosophie*, when he no longer contrasted the concept of form with the concept of content, but with the concept of life. In this later period, forms are the crystallization of the unretainable flow of life, yet also the channels of expressing life, for life cannot be expressed as only itself. Simmel explained this apparent paradox by asserting that life is 'more-life' and also 'more-than-life.' The concept of 'more-life' merely implies that this continuous flow connects every complete moment with the next; 'more-than-life' implies that life is not life if it does not transcend its boundaries, and becomes crystallized in a form. So life becomes art, or science; for example, life becomes externalized and crystallized and hence expressed and fulfilled. For instance, we should understand art as one form of expressing (*äussern*) life through (artistic, aesthetic) forms. Actually uncovering how this perspective can be applied to sociology may appear to be a difficult task; the first step toward clarifying this was made by Simmel himself in his *The Fundamental Questions of Sociology*.

'Me' and 'You'

Deliberately distancing himself from the concept of 'alter ego,' Simmel emphasized the significance the concept of 'you' should

have to all sociological theory. He articulated and embedded this concept within his – sociological – theory of knowledge. In parallel with Kant's question on nature, Simmel formulated this question as 'How is society possible?' – the first and well-known digression of his *Sociology* (1908). In order to answer this question he proposed three a priori. According to the first, 'Me' and 'You' would see each other as 'to some extent generalized' (Simmel, 1992a: 47), and he therefore assumed that each individual's perception of the other (i.e., 'you') would also be generalized to a certain degree. The second a priori affirms that each individual as an 'element of a group is not only a part of the society, but, on top of this, also something else' (Simmel, 1992a: 51) that derives its own uniqueness, its individuality from the duality of being/not being sociated. The third a priori is related to the assignment of each individual to a position within their society (in the sense of the sum of highly differentiated reciprocal actions and effects): 'that each individual is assigned, according to his qualities, to a particular position within his social milieu: that this position, which is ideally suited to him, actually exists within the social whole – this is the supposition according to which every individual lives his social life' (Simmel, 1992a: 59); this is what Simmel meant when he wrote about the 'general value of individuality.'

These sociological a priori, orientated toward role, type, and individual/society, also allow us to understand the central aspects of Simmel's methodology, which can be framed together with the concepts of 'differentiation,' in the sense of division and difference, and of 'dualism,' in the sense of an irreconcilable, tragic opposition of the elements of a social whole.

A Proposal for Three Sociologies

According to Simmel sociology needed to stand as an autonomous science in close relationship with 'the principal problem areas' (Simmel, 1999a: 76–84) of social life, even when these areas were distant from each other. Already in 1895 he asserted that just which name to give to any particular group was quite unimportant, in as much as the real question was to state problems and to solve them, and not at all to discuss the names which we should give to any particular group (Simmel, 1895: 420).

He stressed this orientation into problem areas again in 1917, when he returned to theorizing on *The Fundamental Questions of Sociology*. Thus, as an attempt to approach these main questions (i.e., which relationships exist between society and its elements, individuals) he concentrated on three different sets of problems with concrete examples, particularly in the third part of the first chapter. The first focuses on objectivity as a component of the social sphere of experience; the second includes the actual facts of life, in which, and through which, social groups are realized; and the third emphasizes the significance of society (Fitzi, 1999, 2002; Simmel, 1999a: 84) for grasping and understanding attitudes toward the world and life. These three problem areas correspond to his three proposed sociologies: the 'general sociology,' which, wherever society exists, deals with the central relationships between the individuals and the social constructions resulting from them. The aim of general sociology is to show which reciprocally orientated values these social constructions and individuals possess. He gave an example for general sociology in the second chapter of *The Fundamental Questions of Sociology*, by illustrating the relationships which exist between the 'social and the individual level,' a perspective which, at the same time, sociologizes the masses theory.

The 'pure or formal' sociology focuses upon the multiple forms individuals use to channel contents in their reciprocal actions and effects with others, be it with other people, social groups, or social organizations, and thus they constitute society. According to him, each form wins, entwined in these social processes, 'an own life, a performance, which is free from all roots in contents' (Simmel, 1999a: 106). The example Simmel chose for his formal sociology was the form of 'sociability' (*Geselligkeit*), an elaboration upon this form became the third chapter of *The Fundamental Questions of Sociology*. Finally, the 'philosophical sociology' circles the boundary of the 'exact, orientated toward the immediate understanding of the factual' (Simmel, 1999a: 84) empirical sociology: on the one hand the theory of knowledge (*Erkenntnistheorie*), on the other, the attempts to complement, through hypothesis and speculation, the unavoidably fragmentary character of factual, empirical phenomena (*Empirie*), in order to build a complete whole (Simmel, 1999a: 85). In the fourth chapter, entitled 'The Individual and Society in Eighteenth and Nineteenth Century Views of Life,' Simmel illustrated the abstract necessity of individual freedom, which should be understood as a reaction to the contemporary, increasing, social constraints and obligations. Thus, reference is made to general conflicts between individual and society, which derive from the irreconcilable conflict between the idea of society as a whole, which 'requires from its elements the one-sidedness of a partial function,' and the individual, who knows him/herself to be only partially socialized, and 'him/herself who wants to be whole' (Simmel, 1999a: 123).

Simmel and Contemporary Sociology

Simmel's theoretical significance to contemporary sociology (and to the social sciences in general) resides in the various theories, which explicitly or implicitly are built upon the basis of his works. As examples, it will be sufficient to name symbolic interactionism, conflict theory, functionalism, the sociology of small groups, and theories of modernity. Simmel also introduced into sociology the essay as an academic form of analysis, whilst his digressions within *Sociology* should be mentioned as well, for they have become generally recognized as classical texts; see, for example, his digressions on 'The Letter' (*Brief*), 'Faithfulness' (*Treue*), 'Gratefulness' (*Dankbarkeit*), and 'The Stranger' (*Fremde*). But above all sociology owes Simmel the freedom he gave it from the fixation on the 'individual and society' as an ontic object – in hindsight, a point of no return.

When the first version of this article was written more than 10 years ago (2000), Simmel scholars were still fighting an academic battle for Simmel's recognition as a classical author of sociology, such as Durkheim or Weber. In April 2012, we can

state that this academic battle has been won. Georg Simmel belongs now to the founding fathers of sociology and the social sciences, and is fully recognized as one of the main authors of the classics' generation. This did not happen by chance. It has implied the work of a few sociologists, who have devoted their academic life and work to keeping the memory of Simmel's works, and applying his theoretical lenses to current problems. Otthein Rammstedt discovered Simmel in his years as a student in Frankfurt, especially under the guidance of Gottfried Salomon-Delatour, and he has worked during decades to help young scholars interpret the richness of Simmel's works and legacy, among others breaking stereotypes that were given to students long before they ever read a line of Simmel's original works. Otthein Rammstedt has coordinated and edited Simmel's collected works (24 volumes edited mainly in German which collect the whole of Simmel's works, and all the letters that could be recovered in an arduous research in archives throughout Europe and the USA). The last volume of Simmel's collected works is about to see the light of day, and thus the whole of Simmel's works will be available to the German reading public. At the same time, great efforts have been made to make Simmel's works available in other languages. By the time the first version of this article was published, we were still missing the possibility of a complete translation of *Sociology* into English; 3 years ago this translation was published. David Frisby in the UK and Kurt Wolff and Donald Levine in the USA made great efforts to spread Simmel's works within the English-speaking academic milieu. David Frisby corrected the wrong translation of *Wechselwirkung* for interaction, which had been widely accepted for many years as the only possible way of translating *Wechselwirkung* into English. At the same time, he applied a Simmelian framework to the analysis of modern (and postmodern culture), and city landscapes. Frisby's understanding of Simmel's works as somehow 'impressionistic' and fragmentary was not shared by other Simmel scholars, like, for instance, Otthein Rammstedt, who argued and argues against the stereotype of Simmel's theoretical framework and analyses being fragmentary. At the same time, authors like Klaus Lichtblau or Klaus Christian Köhnke sought to investigate Simmel's relation to his contemporaries, unmasking some myths about Simmel (like for instance that which wrongly stated that he had been a neo-Kantian). Despite minor differences, this generation of scholars worked together to make Simmel's oeuvre available to contemporary social scientists and philosophers. In the meantime, another generation has been able to work upon, and with, Simmel's theories, upon the shoulders of giants – once again. This new generation has focused more prominently upon the relational paradigm in Simmel's works, seeking to apply it, as we understand he would have recommended us to do, to our contemporary sociological problems and questions. (See, for instance, Fitzi, 2002; Papilloud, 2002, 2003; Cantó-Milà, 2005; Phyyhtinen, 2010; Tokarzewska, 2010.)

Furthermore, the anniversaries of the publication of *The Philosophy of Money* first (1900), and *Sociology* later (1908) have also given occasion for the organization of conferences and seminars that have sought to actualize Simmel's works, and discuss the striking validity of most of the theoretical insights he left for us to explore further. (See, for instance, Rammstedt et al., 2003; Rol and Papilloud, 2009.) And, last but not least, Simmel's works have been translated into Spanish, Portuguese, Italian, French, Japanese, Chinese, etc. thus starting a global debate upon his sociological and philosophical legacy.

Abstract

Simon's reputation and legacy are curious and extensive, but opaque. Many talk of bounded rationality without understanding what he meant by it. His 1978 Nobel Prize in economics shocked the economics community, which did not see him as an economist at all. His PhD thesis, eventually published as *Administrative Behavior* has gone to four editions, yet is not much cited by organization theorists today. His work in artificial intelligence is more identifiable, but now regarded as part of the field's history given he left no theory or model in wide use today – with the little known exception of 'list processing,' more due to his collaborator Allan Newell. This article argues Simon was a philosopher, the first of our neo-Weberian organizational world. Bounded rationality is Simon's core philosophical contribution and it provides a new entry point into understanding how firms are able to create new economic value. It is not a model of the human mind. Our present obsession with positivist methodologies prevents us appreciating Simon's work – but its time will come.

Herbert A. Simon's reputation is broad, particularly in the public discourse for 'bounded rationality' is part of the general lexicon, 'satisficing' less so. Simon's permanent place in intellectual history was marked by the 1978 Nobel Prize in Economic Science, but his scholarly impact and legacy is more difficult to establish (Augier and March, 2004; Spender, 2013). Indeed, few economists ever understood how or why Simon won, especially as Sune Carlson, a noneconomist, wrote the commendation and made little mention of economics. Simon's Turing Award, ORSA/TIMS John von Neumann Theory Prize, and National Medal of Science were easier to understand, though the General Problem Solver Simon developed with Allan Newell is forgotten except to historians of artificial intelligence (AI). Newell and Simon's famous claim to have developed a 'thinking machine' over the 1955 Christmas break is forgotten too, though some recall the pair built an early chess-playing program. Others know Simon as a psychologically informed administrative theorist moving beyond the naive organization and management theories laid out by Max Weber or Frederick Taylor, or the behaviorist psychology of Skinner; hence his American Psychological Association Lifetime Achievement Award. His PhD-based book *Administrative Behavior (AB)*, published in 1947 and translated into a dozen languages, is now in its fourth edition. Carlson's Nobel commendation certainly cited *AB* but implied some of the prize was for *Organizations* (March and Simon, 1958), contributions to the 'behavioral theory of the firm,' and for two papers widely regarded as Simon's most substantial theoretical contributions: *A Behavioral Model of Rational Choice* (Simon, 1955) and *Rational Choice and the Structure of the Environment* (Simon, 1956). But none of these works created much change in economics, indeed the term 'bounded rationality' did not appear in *AB* until the 1958 Second Edition's new Foreword. Nonetheless *AB* has been studied by legions of doctoral students, and some masters' students too. Its Chapter 2, a withering attack on the 'proverbs of administration,' was based on a 1946 paper in *Public Administration Review* (Simon, 1946). Yet the proverbs, bureaucratic practices, and Scientific Management survive unscathed as the management practitioner's – and most researchers' – norm. Note also that the citations to *AB* pale in comparison with those to Michael Porter's 1980 *Competitive Strategy* or Jay Barney's 1991 RBV (*resource-based view*) article, indicating the researchers' current norms. Some specialists are aware of Simon's early work in public administration, also now invisible, and that he was awarded the American Political Science Association's Dwight Waldo Award in 1995.

What happened to these achievements and honors? Our inability to identify Simon's legacy today can be contrasted with the eulogies when he died in 2001. There was widespread recognition that a major scholar had passed on, though his precise contribution was difficult to pin down. Most obituaries focused on his AI work. Some obituarists noted his work helped establish that human beings lacked the reasoning capacity neoclassical economists presumed, but the obituaries did not consider the impact of that conclusion. Remarkably few noted he had inflicted irreparable damage to the neoclassical economists' claims, notwithstanding the string of Nobel Prizes awarded to US-based economists such as Paul Samuelson, Kenneth Arrow, Milton Friedman, Gerard Debreu, Franco Modigliani, Gary Becker, and Robert Lucas – rationalists one and all. Clearly little changed in economics; indeed it may be that Simon's lack of impact arises precisely because of the continued presence and power of Chicago-style economics and its associated neoliberal politics, even as those economists' bafflement in 2008 seemed to endorse Simon's charge.

If so, what can be said today? First, Simon successfully kicked open a door others had merely pointed to, most notably by Frank Knight with his *Risk, Uncertainty, and Profit* (Knight, 1921) and the notion of 'Knightian uncertainty.' If economics is to be a source of useful insight into the human condition, a self-sustaining group of scholars will have to pass through the door marked uncertainty into the 'new economics' that Simon anticipated (Coase and Wang, 2012). In the event, and again there are precedents for this, Simon was not able to go there himself. Rather it was as if he had shouted 'FIRE!' and, showing the audience how to escape, had to sacrifice his own project. If that sounds overly dramatic there were profoundly dramatic dimensions to Simon's scholarly life, career, and work, even as his private life was sublimely stable. Thus the most fruitful

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61286-2

reason to study Simon's enormous *oeuvre* is to clarify the potential research areas he pointed toward rather than the common claim that he overturned much in the several different fields he visited. In today's world of shrunken academic debates that contribute little to public understanding, Simon worked as a medieval scholar might on the broadest canvas imaginable – pondering the nature and limits of human understanding and their impact on our personal, economic, and national lives, a topic scoped out for most of the last three centuries by scholars such as Hume, Locke, Kant, and Marx. In spite of writing a vast amount, Simon seemingly wrote to smaller thinkers – academic economists, business school professors, psychologists, and computer scientists – who generally ignored the deeper implications of his work. In this respect Simon, or rather his potential contribution, was probably one of the earlier casualties in the post-World War II struggle to change the US universities. Simon's academic career began in 1942 and flourished in a period during which the US universities made radical changes to their mission and process, matters now emerging as the crisis of US educational performance is attracting both public and governmental concern and the long-term impact of the US' post-World War II policies are undergoing new assessment. Paradoxically, Simon was a fellow traveler with those whose thinking led to these changes and his Nobel may have been a bittersweet token of their regard.

But to begin at the beginning; the Simon parents were from the community of German immigrants settled in Milwaukee. Simon was a hard-working and exceptionally able son who won a full scholarship to the local large university (University of Chicago) after extensive personal study of political and public administration matters, robustly discussed around the dinner table. He arrived at the university in 1933 and took courses in the humanities and the social, physical, and biological sciences. Robert Maynard Hutchins had been appointed President of the university in 1929 and was transforming it by loosening up the prevailing orthodoxies in degree structure and content. Confronting the traditionalists, Hutchins eliminated the football program as a diverting irrelevance and set the stage for the remarkable period of sociological, legal, and political scholarship that lifted the university into the topmost rank. He left to head up the Ford Foundation in 1951, a matter of considerable later import. Meanwhile Simon set about exploiting the university's new curricular flexibilities by auditing upper level courses in several disciplines. He decided to major in economics but discovered it obliged him to take accounting, which he did not care for. He switched to political theory, dipping his toes into psychology, biology, mathematics, research methods, and philosophy – the renowned polymath was evolving. One of his teachers was Henry Simons, a forgotten giant of Chicago economics, and a contemporary of Frank Knight's. Simon wrote the question that was to define his academic *oeuvre* – "How do human beings reason when the conditions for rationality postulated by neoclassical economics are not met?" – came to him 'forcibly' during one of Simons' price theory courses. As a political science student with good insight, Simon intuited politics and administration, perhaps democratic society itself, would be superfluous were people actually like those the neoclassical economists imagined. The insight was not merely the fruitful germ of a critique of most economics, it implied a novel approach to the question "How might real-world decision making and administration be better understood and improved?" Simon said his overall project was to 'stiffen' the prevailing political and sociological discourse by exploring more scientific approaches; to improve the democratic process by ridding it of mere opinion, dogma, and bluster. In 1935, then aged 19 years, Simon wrote an undergraduate course paper on allocating Milwaukee's municipal funds between playground maintenance – such a planting trees and cutting grass – and 'leadership activities' – planning and running neighborhood programs, what we now call a messy or 'wicked' decision that went well beyond data analysis.

The paper led to collaboration with Clarence E. Ridley, head of ICMA (International City/County Management Association) and a manual for city administrators, published in 1936 to widespread acclaim. So Simon's list of publications began; eventually to number around 650. The manual leveraged into a 3-year Rockefeller Foundation funded project on public administration in California where Simon managed a team of mature researchers, his PhD still not completed, though continuing by special arrangement with the Economics Department at Chicago. Simon married in 1937, a relationship that lasted until his death. In 1942, finishing up his degree and California project, the Simons returned to Chicago where he gained an entry-level position at the Illinois Institute of Technology (IIT). After settling into his teaching, he began to recast his PhD thesis into *Administrative Behavior*, circulating about 100 mimeographed copies. One reader who replied at length was Chester Barnard, and so the principal influence over Simon's thinking came into place as he revised the initial drafts substantially. Both Barnard and Simon, of course, rejected naive rationalism and presumed the manager's task was defined by the nonrational aspects of those being managed – bounded rationality being one descriptor – and the consequent need to display 'leadership' as the practice of synthesizing the fragments known into an actionable picture. *Administrative Behavior*, with a Foreword by Barnard, was published in 1947, again to considerable acclaim. Simon was elevated to Full Professor at IIT and invited into the Cowles Commission (then based in Chicago) to do some of the research they funded. This brought him into the tight group of scholars circulating in and out of RAND in Santa Monica, California that included many future Nobel winners – such as Tjallings and Arrow, who later wrote *The Limits of Organization* (Arrow, 1974). In 1949, Simon was tempted away from IIT to help set up the Graduate School of Industrial Administration (GSIA) at Carnegie Institute of Technology (which became Carnegie Mellon University in 1967). He was to work with Lee Bach, the GSIA Dean, and the psychologist Harold Guetzkow, fellow Chicago graduates. Simon was a hot property and held out for a healthy salary and appointment as Head of the Department of Industrial Administration, one of GSIA's two departments.

Simon's vision was to create a top-notch social science department that could compete with Chicago, Harvard, Wharton, and Stanford, and also with the rising number of think tanks like the Cowles Commission and RAND. Equipped with the most scientific techniques and computing resources, and good research funding from the foundations and government agencies, GSIA would make substantial progress toward a synthesis of organization theory, finance, economics,

psychology, and decision science that the previous generation of grand theorists, such as Weber and Parsons, had failed to achieve. The vision was grounded in Hutchins's and later Merriam's notions of multidisciplinary education, in Simon's experience as a Chicago student, and awareness of government-level interest in applying the social sciences to national issues in the post-World War II era. The vision also reflected onto Simon's notion of the professional academic, for he expected everyone on the GSIA faculty to be able to teach an introductory class in each of the school's subject areas. As a result of the combined intellectual horse-power and politically attuned promotional and fund raising efforts of Bach and Simon's colleagues – including Cooper, March, Holt, Modigliani, and Cyert, GSIA sprang from almost nowhere onto the national intellectual scene. Things were good, scientific successes, and glittering prizes were visible on the horizon.

Then two very different events found Simon stuck between them. First, GSIA's success, expansion, and rising visibility attracted further top caliber economists. But the multidisciplinary Chicago of Bach and Simon's time was being rapidly reconstructed into the famed Economics Department of Hayek, Friedman, Stigler (all Nobel winners) and the libertarian Committee on Social Thought. The rationalist economics star rose rapidly and GSIA's incoming young economists had little time for Simon's multidimensional behavioral synthesizing – seeming to be more waffle than hard science. Even though he was a skilled academic administrator and rainmaker, Simon eventually accepted the inevitable and moved from GSIA to the Carnegie Psychology Department – where he invented 'AI' with Allan Newell. This was not Simon's first 'defeat.' In his first field of public administration he found himself facing a carefully orchestrated academic attack from those – especially Dwight Waldo – who regarded the field as demanding much more than the 'stiffened' rigorous methodologies Simon was promoting. What irony – to be rejected by rationalist economists for his insufficiently rigorous theories of decision making and by public policy leaders for being overly rigorous. But while Simon was a tough guy to work around, given his intellectual aggression and polymath capacity to know something about everything, he was always optimistic. The setbacks, which hurt him for the rest of his life, simply made him change course, not pace.

Simon said his meeting with Allen Newell at RAND in 1952 was the second most important event of his life – after meeting his wife Dorothea in 1936. Newell had been trained by Polya of *How to Solve It* and, understanding heuristics, helped Simon to an amazing breakthrough that few others could have made given their rationalist dispositions; to wit, that computers were not the number crunching devices they were generally thought to be by those (such as Johnny von Neumann) who had used them to do ballistics, statistics, or atom bomb computations, but were actually 'symbol processing' machines – and thus could handle heuristics. Simon realized digital computers could be harnessed to his lifelong project. Given bounded rationality, human thought, as opposed to scientific processes, could never be fully captured by Chicago-style rationalist models. On the other hand, it could be addressed by capturing humans' decision-making heuristics in the psychology lab – for these could then be programmed into a computer that cared not one whit about the scientific status of the relationships it was computing. As a chess player and skilled musician Simon realized what had to happen next. Simon had also sketched a chess program in a 1953 RAND report. He arranged for Newell to join him at Carnegie, notionally as his PhD student, and the two worked with Cliff Shaw, who had worked with von Neumann building the JOHNNIAC computer at RAND. Their first project was the Logic Theorist, programming mathematicians' proof-generation heuristic processes. This required a completely new kind of programming – list processing. The group's creation of the first forms of LISP was indeed a considerable innovation, seldom noted though fundamental to the expert systems, visual recognition, and data mining technologies of today's surveillance society. Simon also began to ask colleagues about human financial decision-making protocols and programmed these, underpinning GSIA's most notable academic achievement, the development of the 'behavioral theory of the firm.' The rapidly progressing AI work with Newell and Shaw came to fruition quickly in the 1955 Christmas claim. But once again such rapid academic advances attracted opposing conservative forces, sometimes irrational forces of ignorance and jealousy, sometimes more thoughtful and effectively critical.

Speculation about the nature of human thought goes back as far as history and thinkers like Aristotle, Descartes, Hume, Locke, and Kant had plenty to say. As news of the 'thinking machine' work of the Carnegie AI group spread, many were shocked and disheartened by what seemed to be philosophically uninformed claims to have broken through into a new understanding of human knowledge and learning. Of course those moving in the machine learning direction were greatly heartened, an especially ironic note struck when Simon recommended Kahneman for a Nobel for the work that he and Tversky had been doing on 'prospect theory,' which owed nothing to Simon's own work. But others were appalled, most famously Herbert Dreyfus, America's leading interpreter of Heidegger's work. Dreyfus, too, was drawn into the formative group of scholars circling RAND that went on to transform the American university. The group was not, as some charge, blindly marching in ideological lockstep, but was more of a constellation of some of the nation's smartest scholars, able to generate and handle major critiques of each other's work. Dreyfus's project was to explore and explain the limitations to digital computing. His 1965 report *Alchemy and AI* caused uproar since it implicitly charged RAND and many in its circle with hubris, perhaps the most serious sin a philosopher can commit. Dreyfus's book – likewise ironic since his brother Stuart was also at RAND working on JOHNNIAC – appeared as *What Computers Cannot Do* (1972). The book sparked immediate public discussion and Simon and Dreyfus plunged into a serious academic firefight, eventually calling a truce that revealed they had been talking past each other all along. But Dreyfus's work gave fresh ammunition to those in the struggle between 'hard' and 'soft' AI that is as alive today as it ever was. 'Hard' are those who believe we shall shortly make machines that are 'more intelligent than Man,' and are pitted against the 'soft' who say this is a seriously unintelligent conception of human intelligence. Simon was never able to escape being framed by this contest, though he had little time for either camp. He proposed, instead, that we understand computers as useful (and increasingly powerful) tools to help us make the

best of our bounded rationality, just as we make pulleys to lift heavy weights and books to help our memory. He had high expectations, of course, and was a fascinated geek. Knowing well that chess was a game of programmable heuristics, he famously anticipated a LISP-programmed computer beating the World Chess Champion, as IBM's Deep Blue did, though he did not anticipate the public's hunger for game shows and thus IBM's Watson winning performance.

The other thing that happened was that the very same foundations that had been so ready to fund the research of those circling around RAND were persuaded to insert themselves into the ideological and methodological debate between the rationalists and their philosophically and methodologically broader opponents. Bach appeared for both sides. Having initially supported Simon's vision for a multidisciplinary business school when Simon arrived at GSIA, Bach's support wavered as the political forces within the academic community and their funders began to line up behind neoliberal rationalism, so further inclining Simon to shift over to the Psychology Department. The RAND-centered group made a huge advance with Arrow's 'impossibility theorem,' published in *A Difficulty in the Concept of Social Welfare*, which many saw as conclusive mathematical proof that socialism could not work. Likewise Hayek's *Road to Serfdom* was flying off the shelves. The US' Cold War answer to Communism and other political dogma was to be hard science and rationalism, 'nothing but the facts, Ma'am.' The power of positivist methodologies was being rapidly expanded by the computer's ability to run ever-more complex statistics, and as a consequence expanding the notion that social, economic, and psychological facts could be framed 'objectively.' These methods were 'on the right side of history,' especially in the social sciences, and in the fact that politicians, city managers, and business people were able to make fact- or evidence-based decisions very differently from their forebears. Management of all types was reconceptualized as a 'science.'

From this point of view the business schools were seriously behind the curve, while GSIA was showing the way to the future. Even where accounting was taken seriously, most business schools treated managerial intuition reverently and the new 'science of management' ignored. Bach met with Donald Kirk David, then Dean at the Harvard Business School, later head of the Ford Foundation, and they eventually persuaded both the Carnegie Foundation and the Ford Foundation to fund inquiries and then issue reports on the parlous state of US business education. The reports were damning. Through their recommendations, and the subsequent funding these same foundation provided to those schools that followed their recommendations, the two 1959 reports had a massive and immediate impact. *Inter alia* they legitimated the priority of quantitative methods and modeling aesthetic that many now see as one of business education's main problems. Faculty members were increasingly selected on the basis of their displays of positivist methodological prowess. Whether they knew anything about the practice of managing or industrial operations became secondary. The business schools' business-experienced people were shown the door. Simon sensed he was being encircled professionally and institutionally, seeing his vision for GSIA rejected, but he also saw that he was being encircled disciplinarily, the answers he offered organization theorists, management theorists, and decision theorists in *AB* being rejected too. His only complaint was buried in his 1967 paper *The Business School: A Problem in Organizational Design* (Simon, 1967). This paper was written from the institutional security of his position in the Psychology Department and his professionally secure global reputation in AI. It is somewhat wistful as well as complex. Simon followed Barnard to remind readers that management is about leadership and effective synthesizing under conditions of uncertainty, not the ever-more rigorous application of rationalist theory. Any school of management that fails to provide its students with some understanding of how to deal with the real world's uncertainty is not meeting its pedagogical obligations. But, and this is the crux of the paper, conjoining education in analysis and synthesis within a single school creates great institutional strain; only the very best Deans will be able to contain it and manage it. It is a 'wicked' management problem. Simon had Lee Bach for a model of Deanship, of course, for no matter whether they agreed or not Bach's achievement in lifting GSIA into the top tier of business schools remains unmatched in US business school history (Khurana, 2007). When the strains are not handled effectively faculty members are driven solely by self-interest, which is to say they work toward academic ends within their own disciplines and ignore the students' need for training to operate and lead in real-world multidisciplinary contexts. Simon labeled this an academic tendency to the 'equilibrium' condition – a sly allusion to the poverty of equilibrium economics – and used the analogy of the rising 'entropy'; what effective Deans must struggle to contain. Today's business schools have not been able to deal with the entropic challenge Simon distilled from his own experience, insights, and disappointments.

Thus Simon's life showed a startling contrast between, on the one hand, the steadiness of his family background, his 50-year devotion to Carnegie Mellon (he lived in the same house throughout and became a CMU Trustee, with the Newell–Simon building named for him), and his steady pursuit of a problematic first intuited at the age of 19, and on the other, the prominent part he played in major disputes in three disparate disciplines: public administration, economics, and AI. Few scholars get to play such a role in one. But Simon's achievement in this regard – bridging three disciplines – says something fundamental about his work. The reason he was able to get to grips with the most fundamental questions in three separate field was not that he was bright, perhaps a genius. It was because he approached all these disciplines as Hume and Locke did, in terms of the fundamental puzzle about the nature of human understanding. In this sense, Simon was a modern philosopher who successfully moved beyond the boundaries most others take for granted and leave unquestioned. Although he wrote that he was an empirical positivist it is clear that he was in no way beholden to any positivist thought or method that dismisses synthesis in favor of rigorous deduction. He also grasped synthesizing, the creative nonlogical process of bringing ideas together, perhaps inductively, when dealing with real world's uncertainties. Understanding the complementarity of the methodological issues and disputes in political theory, sociology, and psychology, Simon managed to construct a sustainable and productive intellectual path between them. The glue that held all this thinking together

was his unswerving faith in the human mind's ability to reason and to create anew when reason stumbled. In this he shared much with John Locke, but there is no evidence that he studied Locke's work. More generally, Simon's grasp of multiple disciplines arose from his ability to escape their particular problematic and see them as instances of the larger struggle to understand human understanding itself.

Simon's legacy can be dimly identified in the several different disciplines he touched – public administration, organization and management theory, AI. But there are no memorials, as Scientific Management is a memorial to Frederick Taylor and his colleagues, or the Turing Machine is a memorial to Alan Turing's insight into the nature of computing machines. Perhaps Simon's most visible thumbprint is 'bounded rationality.' But, as many have noted, it is more often cited than understood. Indeed Simon noted at the time of his Nobel, "bounded rationality seemed to be dying a quiet death, in the US at least. The neoclassicists had clearly won the day." Simon's vision for a practical management science – driven by heuristics and 'best practices' rather than by rationalism – has left no mark. Business schools pay less attention to any of Simon's work. All of which suggests Simon's work – and Barnard's too – should be consigned to the trash can of history as nonrational mysticism that is irrelevant in today's data and analytics driven world.

But if we understand Simon primarily as a philosopher, arguably the first philosopher of the strange world of organizations we have created and now inhabit, he has much to say about our current anxieties. Max Weber lamented the 'disenchantment' of our world, increasingly dominated by rationalized processes and objectified values. Without doubt Simon's philosophizing remains out of place in the neoliberal rationalist world created since World War II. The possibilities of Simon's future influence – his promotion of human value- and faith-penetrated heuristics, not just at the level of democratic society but also at the level of organizational decision making, over the cold and lifeless machine logic of numbers ruling – turns on what happens to us when today's neoliberal dream or nightmare passes into our history. By then there may be little left of the Newmanesque University with its quiet probing and prodigious scholarship. Universities may have become little more than fee-earning think tanks and artificers to the government's chosen programs, and decay as their ideology dies. But if there are survivors, they will find great succor in Simon's work. Unlike the great scholars of the past, such as Hume, Locke, and Kant, Simon brought philosophy freshly into the Information Age. He straddled across the scientific territory of rigorous thought and design and the subjectivist territory of creative social thought. He brought the human heuristic maker together with the computer's extraordinary future. He brought human shortcomings and values together with bureaucratic notions of organization. He brought the power of modern data collection and analysis together with the political imperatives of the democratic process. In short, Simon, a masterly thinker of the modern era, showed us a possible future that dismisses those now calling for retraction into an imagined golden past of trust and higher social values. That we doubt the value of his work today is proof positive of our incapacity to see our presently parlous social, economic, and political situation. But as Santayana suggested, history is unkind to the unthinking – and we shall surely learn.

Abstract

An example of simultaneous equations may consist production and consumption functions of a nation: $Y = a + bK + cL +$ error, and $C = d + eY +$ error. In equations, Y is GDP, K is the capital equipment, L is the labor input, and C is the consumption of a nation. Each equation is modeled to explain the variation of the dependent variable by the right-hand side of the equation. Error terms are added since equations cannot fully explain the variation of the dependent variables. This system does not consist of regression equations since Y is in the right-hand side of the C equation. Estimation of unknown coefficients and the properties of estimation methods are complicated compared with the ordinary least squares estimator. In this article, estimation methods of the whole system, and the asymptotic distribution of the estimators are explained first. Then estimation methods of a single equation are explained, and the asymptotic distribution is given. Using the framework of estimators, the small sample distribution by simulations and exact distribution of the single equation estimators are reviewed. Asymptotic expansions of the distributions of the single equation estimators are reviewed next, and finally the higher order efficiency of the system and the single equation estimators are explained.

A simple example of a system of linear simultaneous equations may consist of production and consumption functions of a nation: $Y = a + bK + cL +$ error, and $C = d + eY +$ error. The variables Y, K, L, and C represent the gross domestic product (GDP), the capital equipment, the labor input, and the consumption, respectively.

These variables are measures of the level of economic activity of a nation. In the production function, Y increases if the inputs K and/or L increase. C increases if Y increases in the consumption equation. Each equation is modeled to explain the variation in the left-hand side 'explained' variable by the variation in the right-hand side 'explanatory' variables. Error terms are added to analyze numerically the effect of the neglected factors from the right-hand side of the equation. These equations are different from the regression equations since the 'explained' variable Y is the 'explanatory' variable in the C equation, and Y and C are simultaneously determined by the two equations. Estimation of unknown coefficients and the properties of estimation methods are not straightforward compared with the ordinary least squares estimator.

In practice, this kind of simultaneous equation system is extended to include more than 100 equations, and regularly updated to measure the economic activities of a nation. It is indispensable to analyze numerically the effect of policy changes and public investments.

In this article, the statistical model and the estimation methods of all the equations are first explained, followed by the estimation methods of a single equation and their asymptotic distributions. Explained next are the exact distributions, the asymptotic expansions, and the higher order efficiency of the estimators.

The System of Simultaneous Equations and Identification of the System

We write the structural form of a system consisting of G simultaneous equations as

$$y_i = Y_i\beta_i + Z_i\gamma_i + u_i \equiv (Y_i Z_i)\delta_i + u_i, \quad i = 1, \ldots, G \qquad [1]$$

where y_i and Y_i are 1 and G_i subcolumns in the $T \times G$ matrix of whole endogenous variables $Y = (y_i, Y_i, Y_{ei})$, Z_i consists of K_i subcolumns in the $T \times K$ matrix of whole exogenous variables Z, β_i and γ_i are $G_i \times 1$ and $K_i \times 1$ column vectors of unknown coefficients, $\delta_i = (\beta'_i, \gamma'_i)'$, and u_i is the $T \times 1$ error term. This system of G equations with T observations is frequently summarized in a simple form

$$YB + Z\Gamma = U \qquad [2]$$

the ith column of which is $y_i - Y_i\beta_i - Z_i\gamma_i = u_i$, i.e., Eqn. [1]. The ith columns of B and Γ may be denoted as b_i and c_i where $(G - G_i - 1)$ and $(K - K_i)$ elements are zero so that $y_i - Y_i\beta_i - Z_i\gamma_i = Yb_i + Zc_i$. Zero elements are called zero restrictions. It is assumed that each row of U is independently distributed as $N(0, \sum)$. The reduced form of Eqn. [2] is

$$Y = Z\Pi + V \qquad [3]$$

where the $K \times G$ reduced form coefficient matrix is $\Pi = -\Gamma B^{-1}$, and the $T \times G$ reduced form error term is $V = UB^{-1}$. Each row of V is assumed to be independently distributed as $N(0, \Omega)$, and then $\sum = B^{-1}, \Omega B^{-1}$.

The definition $\Pi = -\Gamma B^{-1}$, or $-\Pi B = \Gamma$ is the key to identify structural coefficients. Coefficients in β_i are identified if they can be uniquely determined by the equation $-\Pi b_i = c_i$ given Π. This equation is reduced to $-\Pi_0(1, \beta'_i)' = 0$ denoting the $(K - K_i) \times (1 + G_i)$ submatrix in Π as Π_0. (Rows and columns are selected according to the zero elements in c_i and non-zero elements in b_i, respectively.) Given Π_0, this includes $(K - K_i)$ linear equations and G_i unknowns, and β_i is solvable if rank $(\Pi_0) = G_i$. This means $(K - K_i)$ must be at least G_i, or $L = K - K_i - G_i$ must be at least 0. If $L = 0$, β_i is uniquely determined. For the positive L, there are L linearly dependent rows in Π_0 since only G_i rows are necessary to determine β_i uniquely. Once β_i is determined, γ_i is determined by other K_i equations through $-\Pi b_i = c_i$. L is called the number of the degrees of overidentifiability of the ith equation. Structural coefficients are not uniquely estimable if they are not identified (see Statistical Identification and Estimability).

Estimation Methods of the Whole System and the Asymptotic Distribution

The full information maximum likelihood (FIML) estimator of all nonzero structural coefficients δ_i, $i = 1,\ldots, G$, follows from Eqn. [3]. Since it is in a linear regression form, the likelihood function can first be minimized with respect to Ω. Once Ω is replaced by the first-order condition, the likelihood function is concentrated where only B and Γ are unknown. The concentrated likelihood function is proportional to

$$\ln|\Omega_R|, \Omega_R = (Y - Z\Pi_R)'(Y - Z\Pi_R)/T, \quad \Pi_R = -\Gamma B^{-1}, \qquad [4]$$

and all zero restrictions are included in B and Γ matrices. In the FIML estimation, it is necessary to minimize $|\Omega_R|$ with respect to all non-zero structural coefficients.

The FIML estimator is consistent, and the asymptotic distribution is derived by the central limit theorem. Stacking δ_i, $i = 1,\ldots, G$ in a column vector δ, the FIML estimator δ asymptotically approaches $N(0, -I^{-1})$ as follows:

$$\sqrt{T}\left(\widehat{\delta} - \delta\right) \xrightarrow{D} N\left(0, -I^{-1}\right), \quad I = \lim_{T\to\infty} \frac{1}{T} E\left(\frac{\partial^2 \ln|\Omega_R|}{\partial\delta\, \partial\delta'}\right). \qquad [5]$$

I is the limit of the average of the information matrix, i.e., $-I^{-1}$ is the asymptotic Cramer–Rao lower bound. Then the FIML estimator is the best among consistent and asymptotically normal (BCAN) estimators.

The right-hand side endogenous variable Y_i in (1) is defined by a set of G_i columns in (3) such as $Y_i = Z\Pi_i + V_i$. By the definition of V, Y_i or, equivalently, V_i is correlated with u_i since columns in U are correlated with each other. The least squares estimator applied to (1) is inconsistent because of the correlation between Y_i and u_i. Since Z is assumed to be not correlated with U in the limit, Z is used as K instruments in the instrumental variable method estimator. Premultiplying Z' to (1), it follows that

$$\begin{aligned} Z'y_i &= \left(Z'Y_i, Z'Z_i\right)\delta_i + Z'u_i \\ &= \left(0, \ldots, 0, Z'Y_i, Z'Z_i, 0, \ldots, 0\right)\delta + u_i^*, \quad i = 1, \ldots, G \end{aligned} \qquad [6]$$

where the $K \times 1$ transformed right-hand side variables $Z'Y_i$ is not correlated with $u^*{}_i$ in the limit. Stacking all G transformed equations in a column form, the G equations are summarized as $w = X\delta + u^*$ where w and u^* stack $Z'y_i$ and $u^*{}_i$, $i = 1,\ldots, G$, respectively, and are $GK \times 1$. The covariance between $u^*{}_i$ and $u^*{}_j$ is $\sigma_{ij}(Z'Z)$ which is the ith row and jth column sub-block in the covariance matrix of u^*. (The whole covariance matrix can be written as $\sum\otimes,(Z'Z)$ where $\otimes$, signifies the Kroneker product.) Once $\sum$ is estimated consistently (by the 2SLS method explained in the next section), δ is efficiently estimated by the generalized least squares method

$$\widehat{\delta}_{3SLS} = \left\{X'\left[\widehat{\Sigma}^{-1} \otimes (Z'Z)^{-1}\right]X\right\}^{-1}\left\{X'\left[\widehat{\Sigma}^{-1} \otimes (Z'Z)^{-1}\right]w\right\}. \qquad [7]$$

This is the three-stage least squares (3SLS) estimator by Zellner and Theil (1962). The assumption of the normal distribution error is not required in this estimation. The 3SLS estimator is consistent and is BCAN since it has the same asymptotic distribution as the FIML estimator.

Estimation Methods of a Single Equation and the Asymptotic Distribution

An alternative way of estimating structural coefficients is to pick up one structural equation, the ith, in a G-equation system, and estimate δ_i neglecting zero restrictions in other equations. Because of this, the other $(G - 1)$ structural equations can be rewritten equivalently as $(G - 1)$ reduced form equations. The limited information maximum likelihood (LIML) estimator by Anderson and Rubin (1949) applies the FIML method to a $(1 + G_i)$-equation system consisting of (1) and $Y_i = Z\Pi_i + V_i$. This means the first column and the second G_i columns of B are $(1, -\beta'_i)'$ and $(0, I)'$, respectively, and the first column and the second G_i columns of Γ are $(\gamma'_i, 0')'$ and Π_i, respectively. (If we denote Y as (y_i, Y_i, Y_{ei}), Y_{ei} is weakly exogenous in estimating (1) or, equivalently, the structural and reduced form parameters of (y_i, Y_i) given Y_{ei} are variation-free from the reduced form coefficient of Y_{ei}. Then Y_{ei} is omitted from (2), (3), (4), and (8).) Using these limited information B and Γ matrices, we minimize $|\widehat{\Omega}_R|$ with respect to δ_i and Π_i. Defining $P_F = F(F'F)^{-1}F'$ for any full column matrix F, $G = (y_i, Y_i)'(P_Z - P_{Z_i})(y_i, Y_i)$, and $C = (y_i, Y_i)'(I - P_z)(y_i, Y_i)$, it turns out that β_i is estimated by minimizing the least variance ratio

$$\lambda(\beta_i) = \frac{\left(1, -\beta'_i\right)G\left(1, -\beta'_i\right)'}{\left(1, -\beta'_i\right)C\left(1, -\beta'_i\right)'} \qquad [8]$$

γ_i is estimated by the least squares method applied to (1) replacing β_i with the estimator.

The two stage least squares (2SLS) estimator is the generalized least squares estimator applied to Eqn. [6] using $Z'Z$ as the weight matrix. (See Eqn. [10], where k is set to 1.) The assumption of the normal distribution of the error term is not required in this estimation. Both LIML and 2SLS estimators are consistent, and the large sample distribution is

$$\sqrt{T}\left(\widehat{\delta}_i - \delta_i\right) \xrightarrow{D} N\left(0, -I^{-1}\left(\delta_i, \delta_i\right)\right) \qquad [9]$$

where I is calculated similarly to Eqn. [5] but Ω_R is defined using the limited information B and Γ matrices, and only the diagonal submatrix of I^{-1} which corresponds to δ_i is used. (Partial derivatives are calculated with respect to δ_i and columns in Π_i.) This asymptotic distribution is a particular case of Eqn. [5]. Both estimators are consistent and BCAN under the zero restrictions imposed on Eqn. [1].

The k-class estimator $\widehat{\delta}_i(k)$ unifies both LIML and 2SLS estimators (Theil 1961). It is

$$\begin{aligned} \widehat{\delta}_i(k) = &\begin{pmatrix} Y_i'P_zY_i - (k-1)Y_i(I - P_z)Y_i & Y_i'Z_i \\ Z_i'Y_i & Z_i'Z_i \end{pmatrix}^{-1} \\ &\times \begin{pmatrix} Y_i'P_z - (k-1)Y_i'(1 - P_z) \\ Z_i' \end{pmatrix} y_i. \end{aligned} \qquad [10]$$

This is the least squares estimator, the 2SLS estimator, and the LIML estimator when k is 0, 1, and $1 + \lambda$, respectively. There are two important properties in the k-class estimator. It is consistent if $p\lim_{T\to\infty} k = 1$, and is BCAN if $p\lim_{T\to\infty}\sqrt{T}(k - 1) = 0$. If k satisfies these conditions, the k-class estimator is consistent

and BCAN even when $Y_i'(I - P_z)Y_i$ and $Y'_i(I - P_Z)y_i$ are replaced with any matrix and a vector of order $O_P(T)$.

Exact Distributions of the Single-Equation Estimators

Several early studies compared the bias and mean squared errors of OLS, LIML, 2SLS, FIML, and 3SLS estimators by the Monte Carlo simulations since all but OLS estimators are consistent and are indistinguishable. The OLS estimator was often found as reliable as other consistent estimators. Later, the studies went on to t ratios, and the real defect of OLS estimators was found: the deviation from the standard normal distribution is worse than any other simultaneous equation methods. See Cragg (1967) for related papers.

Drawing general qualitative comparisons from simulations is difficult since simulations require setting values of all population parameters. Simulation studies on the small sample properties led to the derivation of the exact distributions, which were expected to permit the drawing of general comparisons without depending on the particular parameter values.

If $n \times 1$ column vectors x_t, $t = 1,\ldots, T$ are independently distributed $N(m_t, \Omega)$, the density function of $\Sigma_{i=1.T} x_i x_i'$ is the noncentral Wishart matrix denoted as $W_n(T, \Omega, M)$ where the noncentrality parameter is $M = \Sigma_{t=1,T}\ m_t m'_t$ (Anderson, 1958, Chap. 13). The study of the exact distribution of the single-equation estimators started from the fact that $G = (G_{kl})$ and $C = (C_{kl})$, k, $l = 1,\ldots, 1 + G_i$ in Eqn. [8] are the noncentral Wishart matrix $W_{1+G}(K - K_i, \Omega, M)$ with the noncentrality parameter matrix $M = \Pi_R' Z'(P_z - P_z)Z\Pi_R$, and the central Wishart matrix $W_{1+G}(T - K, \Omega, 0)$, respectively. The 2SLS, OLS, and LIML estimators of β_i are $G_{22}^{-1}G_{21}$, $(G_{22} + C_{22})^{-1}(G_{21} + C_{21})$, and $(G_{22} - \lambda C_{22})^{-1}(G_{21} - \lambda C_{21})$, respectively, and λ is the minimum root in the polynomial equation $|G - \lambda C| = 0$. Since all estimators are functions of elements in the G and C matrices, their distributions can be characterized by degrees of freedom of the two Wishart matrices, M and Ω matrices.

In deriving the exact density functions, the 2SLS and OLS estimators can be treated in a similar way. In the 2SLS estimator, the joint density of G is transformed into the joint density of $G_{22}^{-1}G_{21}$, $G_{11} - G_{12}\, G_{22}^{-1}\, G_{21}$, and G_{22}. Integrating out $G_{11} - G_{12}\ G_{22}^{-1}G_{21}$ and G_{22} results in the joint density of $G_{22}^{-1}G_{21}$. The resulting density function includes infinite terms, and zonal polynomials when G_i is greater than one. A pedagogical derivation is found in Press (1982, Chap. 5). In the LIML estimator, the joint density of G and C is transformed into that of characteristic roots and vectors. Since $\hat{\beta}$ is rewritten as a ratio of elements in a characteristic vector, the density function is derived by integrating out unnecessary random variables from the joint density function. However, the analytical operations are not easy when there are many endogenous variables. See Phillips (1983, 1985) to find comprehensive reviews on the 2SLS and LIML estimators, respectively.

It was somewhat fruitless to derive exact distributions because these include nuisance parameters and infinite terms. It was difficult to draw general conclusions on the qualitative properties of the estimators from the numerical evaluations of these distributions. See Anderson et al. (1982).

Qualitative properties of the estimators followed from the exact moments of estimators. Kinal (1980) proved that the (fixed) k-class estimator in a multiple endogenous variables case has moments up to $(T - K_i - G_i)$ if $0 \le k < 1$, and up to L if $k = 1$. Mariano and Sawa (1972) proved that, in the $G_i = 1$ case, the mean and variance of the LIML estimator do not exit. (In Monte Carlo simulations, the bias of LIML estimators was often found to be smaller than that of others even though the exact mean is infinite. This showed the clear limitation of the simulation methods.)

Asymptotic Expansions of the Distributions of the Single-Equation Estimators

Asymptotic expansion of the distribution was introduced as an analytical tool which is more accurate than the asymptotic distribution but is less complicated than the exact distributions. For instance, the t ratio statistic, say X, which is commonly used in econometrics, has the density function $f(x) = c\cdot[1 + (x^2/m)]^{-(1+m)/2}$ where c is a constant and m is the degree of freedom under conditions including the normally distributed error terms. Since the mean and variance of X is 0 and $m/(m–2)$, the standardized statistic $Z = \sqrt{(m-2)/m}\cdot X$ has the density $f(z) = c'\cdot[1 + (z^2/(m-2))]^{-(1+m)/2}$ where c' is a new constant. This density function is expanded to the third-order term as

$$f(z) = \phi(z)\left\{1 + \frac{1}{4m}\left(z^4 - 6z^2 + 3\right)\right\} + o\left(m^{-1}\right) \qquad [11]$$

where $\phi(z)$ is the standard normal density function, and the constant is adjusted so that the area under the curve is one. (Since the t distribution is symmetric around the origin, the $O(1/\sqrt{m})$ term does not appear in the right-hand side of the equation.) Rewriting in terms of X, the asymptotic expansion of the t statistic with m degrees of freedom is

$$f(x) = \phi(x) + \frac{1}{4m}\left(x^4 - 2x^2 - 1\right)\phi(x) + o\left(m^{-1}\right) \qquad [12]$$

The first term in the right-hand side is the $n(0, 1)$ density function. The second term in the right-hand side converges to zero if the limit is taken with respect to m. This second term gives deviation of $f(x)$ from $\phi(x)$, and is called the third-order term. For finite m, the third-order term is expected to improve the standard normal approximation. The numerical evaluation of this expansion is easy.

The asymptotic expansions in the simultaneous equation estimators are long and include nuisance parameter matrices such as q below. See Phillips (1983) for a review and Phillips (1977) for the validity of expansion. The asymptotic expansion does not require the assumption of the normal distribution of the error term. Fujikoshi et al. (1982) gave the expansion of the joint density of the estimators of δ_i. In their study, the bias of the estimators is calculated from the asymptotic expansions as

$$AM\left(\sqrt{T}\left(\hat{\delta}_i - \delta_i\right)\right) = \frac{1}{\sqrt{T}}(dL - 1)I^{-1}q + o\left(T^{-1}\right), \quad q = \frac{1}{\sigma^2}\begin{pmatrix}\varpi_{21} - \Omega_{22}\beta_i \\ 0\end{pmatrix}, \qquad [13]$$

where $\hat{\delta}$ is the estimator, d is 1 and 0 fo1r 2SLS and LIML estimators, respectively, and the Ω matrix is partitioned into submatrices conformable with the partitions of G and C matrices. $AM(\cdot)$ stands for the mean operator, but uses the asymptotic expansion for the density function. (Recall that the exact mean does not exist in the LIML estimator.) It is possible to compare the two estimators in terms of the calculated bias. For example, the bias of the 2SLS estimator is 0 when the degree of overidentifiability L is 1.

Further, the mean of the squared errors was calculated from the asymptotic expansions and used to compare estimators. It was proved that the mean squared error of the 2SLS estimator is smaller than that of the LIML estimator when L is less than or equal to 6. Historically, this kind of comparison of 'approximate' mean squared errors goes back to the 'Nagar expansion' by Nagar (1959) and the 'small disturbance expansion' by Kadane (1971). These qualitative comparisons gave researchers some guidance about the choice of estimators.

It was interesting to examine the accuracy of the approximations calculated by the asymptotic expansions of distributions. If the asymptotic expansions were accurate, calculation of the exact distributions could be avoided, and properties of estimators could be found easily from the approximations. However, the approximations were found not to be accurate enough to replace the exact distributions. There are many cases where the asymptotic expansion is accurate when the asymptotic distribution, the first term in the expansion, is already accurate; the asymptotic expansion is inaccurate when the asymptotic distribution is inaccurate. In particular, the asymptotic expansions are inaccurate when

a. The value of asymptotic variance is small;
b. The value of L is large; or
c. The structural error term is highly correlated with the right-hand side endogenous variable.

It is noted, first, $Z'Z/T$ is assumed to converge a nonsingular fixed matrix in the asymptotic theory. Second, for an attempt to improve the accuracy of asymptotic distributions by incorporating large L values, see Morimune (1983). Third, the asymptotic expansions cannot trace closely the skewed exact distributions that happen particularly when the correlation is high.

Higher-Order Efficiency of the System and the Single-Equation Estimators

The asymptotic expansions of distributions can be used in comparing the probabilities of concentration of estimators about the true parameter values. One estimator is more desirable than another if its probability is greater than that of the other. This measure was used in comparing the single-equation estimators, and some qualitative results were derived.

Furthermore, the third-order efficiency criterion was brought in the comparisons. This criterion requires that estimators be adjusted to have the same asymptotic bias as in Eqn. [13]. Then the adjusted estimators are compared, and the maximum likelihood estimator is proved most efficient. It has the highest concentration about the true parameter values in terms of the asymptotic expansion of distribution to the third-order $O(1/T)$ terms. (Akahira and Takeuchi, 1981, for example.) The adjusted maximum likelihood estimator has the smallest mean-squared error at the same time since the difference among estimators is found only in the mean-squared errors.

In whole system estimation, the FIML estimator is third-order efficient. The 3SLS estimator is less efficient than the FIML estimator in terms of the asymptotic probability of concentration once the bias of the two estimators is adjusted to be the same. Morimune and Sakata (1993) derived a simple adjustment of the 3SLS estimator so that the adjusted estimator has the same asymptotic expansion as the FIML estimator to the third-order $O(1/T)$ terms. This estimator is explained by modifying Eqn. [7]. In Eqn. [6], Y_i is replaced by $\hat{Y}_i \equiv Z\hat{\Pi}_i = Z(Z'Z)^{-1}Z'Y_i$ so that the X matrix consists of $Z'\hat{Y}_i$ and $Z'Z_i$. In the modified estimator, we estimate $\tilde{\Sigma}$ and Π by the first round 3SLS estimator and replace $\hat{Y}_i$ in X by $\tilde{Y} \equiv Z\tilde{\Pi}_i$ where $\tilde{\Pi}_i$ consists of proper subcolumns in $\tilde{\Pi} = -\hat{\Gamma}\hat{B}^{-1}$. The new X matrix is denoted as $\tilde{X}$. Finally, the new estimator is

$$\tilde{\delta}_{\mathrm{M3SLS}} = \left\{\tilde{X}'\left[\tilde{\Sigma}^{-1} \otimes (Z'Z)^{-1}\right]X\right\}^{-1}\left\{\tilde{X}'\left[\tilde{\Sigma}^{-1} \otimes (Z'Z)^{-1}\right]w\right\}. \quad [14]$$

This estimator has the same asymptotic expansion as the FIML estimator to the third-order terms and is third-order efficient.

The LIML and 2SLS estimators are simple cases of the FIML and 3SLS estimators, respectively. Then the modified 2SLS estimator which follows from Eqn. [14] has the same asymptotic expansion as the LIML estimator to the third-order term. The LIML estimator and the modified 2SLS estimator are third-order efficient in the single-equation estimation.

Conclusion

Laurence Klein received the 1980 Nobel prize for the creation of a macroeconometric model which is an empirical form of a simultaneous equation system, and for the application to the analysis of economic fluctuations and economic policies. The macroeconometric model became a standard tool to analyze the economies and policies of nations. Trygve Haavelmo received the 1989 Nobel prize for his contribution in the analysis of simultaneous structures. Haavelmo, together with other researchers at the Cowles Commission for Research in Economics, then at the University of Chicago, became the founders of simultaneous equation analysis in econometrics. Part of their research is collected in Hood and Koopmans (1953). Studies on the exact and approximate distributions of estimators came after the research conducted at the Cowles group, and helped to make econometrics rigorous.

Access to computers was the main concern when econometric model-building started spreading all over the world in the 1970s. Since then, computer facilities surrounding econometric model-building have changed greatly. Bulky mainframe computer have been replaced by personal computers. Computer programs were written individually, mostly in Fortran, and were used for regression analyses in model estimation as well as for simulation studies in econometrics theory. The packaged least squares programs replaced the individually written programs later in model estimation. They

run on personal computers and have facilitated greatly the conducting of empirical studies.

Abstract

Simultaneous equations abound in economics and elsewhere. The simplest economic model uses a supply equation and a demand equation to determine the price of a good and its quantity sold. Neither equation alone can determine either variable when each equation contains both: this is a model with two simultaneous equations. Estimates of the parameters of simultaneous equations are often needed. Parameters can be estimated only if the model and data together are capable of revealing their values, that is, if parameters are identifiable. Examples of identifiable and unidentifiable parameters are presented. For simultaneous equations, least squares regression estimators are typically biased and inconsistent (that is, incorrect on the average in repeated trials, and unlikely to be nearly correct even in large samples). Hence other estimators have been developed that, under suitable conditions, are unbiased in large samples, and consistent. Examples of such estimators are given: indirect least squares, instrumental variables, and two stage least squares. Other such estimators are briefly described: full information maximum likelihood, three stage least squares, and a Bayesian estimator. The particulars of a simultaneous equations model are crucial for its estimation and use, and are unlikely to be quite correct. Relevant tests are briefly discussed.

Simultaneous equations are important tools for understanding behavior when two or more variables are determined by the interaction of two or more relationships in such a way that causation is joint rather than unidirectional. Such situations abound in economics, but also occur elsewhere. Haavelmo (1943, 1944) began their modern econometric treatment.

The simplest economic example is the interaction of buyers and sellers in a competitive market which jointly determines the quantity sold and price. Another important example is the interaction of workers, consumers, investors, firms, and government in determining the economy's output, employment, price level, and interest rates, as in macroeconometric forecasting models. Even when one is interested only in a single equation, it often is best interpreted as one of a system of simultaneous equations.

Strotz and Wold (1960) argued that in principle every economic action is a response to a previous action of someone else, but even they agreed that simultaneous equations are useful when the data are yearly, quarterly, or monthly, because these periods are much longer than the typical market response time.

This article discusses the essentials of simultaneous equation estimation using a simple linear example.

A Simple Supply–Demand Example

Let q and p stand for the quantity sold and price of a good, y and w for the income and wealth of buyers (assumed independently determined), u_1 and u_2 for unobservable random shocks, and Greek letters for unknown constant parameters. Suppose that market equilibrium, in which the price is such that suppliers want to sell the same quantity that demanders what to buy, is described by these linear equations:

$$\text{supply:} \quad q = \gamma_1 + \beta_1 p + u_1, \quad \beta_1 > 0 \qquad [1]$$

$$\text{demand:} \quad q = \gamma_2 + \delta_2 y + \varepsilon_2 w + \beta_2 p + u_2, \quad \beta_2 < 0 \qquad [2]$$

Neither equation alone can determine either p or q, because each equation contains both: these are *simultaneous equations*. Solve them for p and q thus:

$$p = \pi_{11} + \pi_{12} y + \pi_{13} w + (u_2 - u_1)/\Delta \qquad [3]$$

$$q = \pi_{21} + \pi_{22} y + \pi_{23} w + (\beta_1 u_2 - \beta_2 u_1)/\Delta \qquad [4]$$

where

$$\pi_{11} = (\gamma_2 - \gamma_1)/\Delta, \quad \pi_{12} = \delta_2/\Delta, \quad \pi_{13} = \varepsilon_2/\Delta \qquad [5]$$

$$\pi_{21} = (\beta_1\gamma_2 - \beta_2\gamma_1)/\Delta, \quad \pi_{22} = \beta_1\delta_2/\Delta, \quad \pi_{23} = \beta_1\varepsilon_2/\Delta \qquad [6]$$

and

$$\Delta = \beta_1 - \beta_2 \qquad [7]$$

Types of Variables: Structural and Reduced Form Equations

The variables p and q which are to be explained by the model are *endogenous*. Equations [1] and [2] are structural equations. Each of them describes the behavior of one of the building blocks of the model, and (as is typical) contains more than one endogenous variable. Equations [3] and [4] are reduced form equations. Each of them contains just one endogenous variable, and determines its value as a function of parameters, shocks, and explanatory variables (here y and w).

The explanatory variables are predetermined if the shocks for any given period are independent of the explanatory variables for that period and all previous periods; they are *exogenous* if the shocks for each period are independent of the explanatory variables for every period. Thus all exogenous variables are predetermined, but not conversely. For example, the value of an endogenous variable from a previous period

cannot be exogenous, but it is predetermined if the shocks are serially independent.

The Need for Estimation of Parameters

One job of a reduced form equation is to tell how an endogenous variable responds to a change in any predetermined or exogenous variable. Typically, no single structural equation can do this. Another job of a reduced form equation is to forecast the value of an endogenous variable in a future period, based on expected future values of the predetermined and exogenous variables and of the shocks (the latter can safely be set at zero in most cases). Typically, no single structural equation can do this either. If the reduced form equations are to do these jobs, numerical values of their parameters are needed (in this example, values of the π's in eqns [3] and [4]).

Numerical values of the structural parameters are needed as well (in this example, the β's, γ's, δ_2, and ε_2 in eqns [1] and [2]). There are several reasons. First, one wants to understand each of the system's separate building blocks in its own right. Second, in overidentified cases (*see* section 'Estimating One Structural Equation at a Time') better estimates of the reduced form can be obtained by solving the estimated structure (as in eqns [5]–[7]) than by estimating the reduced form directly. Third, if forecasts made by the reduced form are poor, one wants to know which of the structural equations fit the forecast-period's data poorly, and which (if any) fit well. This is discovered by inserting observed values of the variables into each estimated structural equation to obtain an estimate of its forecast-period shock. Then one can revise the poorly fitting structural equation(s) and so try to improve the model's accuracy (*see* section 'The Problem of Choosing and Testing a Model'). Fourth, if one wants to find the new values of the reduced form parameters after a change in a structural parameter, one needs to know the old values of all the structural parameters, as well as the new value of the one that has changed. In the example, one can then use eqns [5]–[7] to compute the reduced form parameters. The critique of Robert Lucas (1976) provides a warning about pitfalls in doing this.

Least Squares Estimators

Least squares (LS) estimators (*see* Linear Hypothesis) of an equation's coefficients are biased if the shocks in each period are not independent of the explanatory variables in all periods. Clearly this is true of eqns [1] and [2], since eqns [3] and [4] show that both u_1 and u_2 influence both p and q. This is typically true of LS estimators of simultaneous structural equations. However, LS estimators often have small variances, so they may sometimes have acceptably small expected squared errors even when they are biased.

LS estimators of the π's in the reduced form, eqns [3] and [4], are unbiased if the shocks in each period have zero mean and constant variance, and are independent of y and w for all periods (so that y and w are exogenous). They have minimum variance among unbiased estimators and are consistent if in addition the shocks are uncorrelated across time. They remain consistent if the shocks are uncorrelated across time but y and w are predetermined rather than exogenous.

The generalized least squares (GLS) method is minimum variance unbiased if the explanatory variables are exogenous but the shocks are correlated across time. This method requires information about the variances and covariances of the shocks.

The Identifiability of Structural Parameters

Having estimates of the reduced form parameters, one can try to make them yield estimators of the structural parameters. In the example this means trying to solve the estimated version of eqns [5] and [7] for estimators of the γ's, β's, δ_2, and ε_2. Denote the LS estimators of the π's by $\widehat{\pi}$. Equations [5] and [6] show that $\widehat{\pi}_{22}/\widehat{\pi}_{12}$ is one estimator of β_1, and $\widehat{\pi}_{23}/\widehat{\pi}_{13}$ is another. Either of them leads to an estimator of γ_1 in eqn [1]. These are indirect least squares (ILS) estimators. They are not unbiased, but they are consistent if the LS reduced form estimators are consistent. The supply parameters β_1 and γ_1 are *identified*, meaning that the data and the model reveal their values (subject to sampling variation). Indeed, they are *overidentified*, because in small samples the two ways to estimate β_1 from $\widehat{\pi}'$s yield different results. (If either δ_2 and ε_2 were zero, there would be only one way, and the supply equation would be *just identified*. If both δ_2 and ε_2 were zero, there would be no way, and the supply equation would be *unidentified*.) Eqns [5]–[7] have an infinite number of solutions for the demand parameters β_2, γ_2, δ_2, and ε_2. Hence the data and the model do not reveal their values; they are unidentified.

Another way to see this is to imagine price and quantity data being generated by intersections of the supply and demand curves in the pq plane. Ignoring shocks, the supply curve is fixed, but the demand curve shifts when y or w changes. Hence the intersections reveal the slope and position of the supply curve as the demand curve shifts. But they reveal nothing about the slope of the demand curve.

The identifiability of parameters is crucial: they cannot be estimated if they are not identified. Reduced form parameters are usually identified, except in special cases. But the identifiability of structural parameters should be checked before one tries to estimate them. The LS formula can be applied to an unidentified structural equation such as eqn [2], but the result is not an estimator of that equation. For a more detailed and general discussion, *see* Statistical Identification and Estimability.

Simultaneous Equations Estimation Methods

Many methods have been developed for estimating identifiable parameters of simultaneous structural equations without the bias and inconsistency of LS. Most of them exploit the assumed independence between shocks and predetermined variables. Some estimate one equation at a time, and others estimate the whole system at once.

Estimating One Structural Equation at a Time

The ILS method mentioned above is one way of estimating one equation that is part of a system. A second way is the instrumental variables (IV) method (Durbin, 1954). LS and

IV will be shown for eqn [1]. Denote the deviation of each variable from its sample mean by an asterisk, for example, $p^* = p - \bar{p}$. Now rewrite eqn [1] in terms of deviations from sample means, thus eliminating the constant term γ_1; multiply it by p^*; sum it over all the sample observations; and divide the sum by $\sum p^{*2}$. The result is the LS estimator *of* β_1:

$$\widehat{\beta}_1 = \sum q^* p^* \Big/ \sum p^{*2} = \beta_1 + \sum u_1^* p^* \Big/ \sum p^{*2} \qquad [8]$$

It is biased and inconsistent because the shock u_1 influences p via eqn [3] so that the error term, the last term in eqn [8], does not equal zero in expectation or in probability limit.

Now rewrite eqn [1] as before in terms of deviations from sample means, but this time multiply it by y^*, sum it over all observations, and divide by $\sum p^* y^*$. The result is an IV estimator of β_1:

$$\widehat{\beta}_{1y} = \sum q^* y^* \Big/ \sum p^* y^* = \beta_1 + \sum u_1^* y^* \Big/ \sum p^* y^* \qquad [9]$$

If y is predetermined it is an *instrument*. In this case the IV estimator is consistent if u_1 has zero mean and constant variance and is serially independent, because then $\sum u_1^* y^*$ is zero in probability limit and $\sum p^* y^*$ is not. Similarly, if w is predetermined it is another instrument, and another IV estimator of β_1 is $\widehat{\beta}_{1w} = \sum q^* w^* / \sum p^* w^*$. Clearly, these IV estimators are equivalent to the ILS estimators of β_1 obtained earlier. For example, the one based on the reduced form coefficients of y is.

$$\begin{aligned} \widehat{\pi}_{22}/\widehat{\pi}_{12} &= \left(\sum q^* y^* \Big/ \sum y^{*2}\right) \Big/ \left(\sum p^* y^* \Big/ \sum y^{*2}\right) \\ &= \sum q^* y^* \Big/ \sum p^* y^* = \widehat{\beta}_{1y} \end{aligned} \qquad [10]$$

Similarly, the other one is $\widehat{\pi}_{23}/\widehat{\pi}_{13} = \widehat{\beta}_{1w}$. For a reduced form equation, IV is the same as LS, because the instruments are precisely the equation's predetermined variables.

The two-stage least squares (2SLS) method (Theil, 1972; Basmann, 1957) is another way of estimating one structural equation at a time. For an overidentified equation it is superior to ILS or IV because it results in one estimator rather than two or more; for a just identified equation it reduces to ILS and IV. It first computes the LS estimator of the reduced form equation for each endogenous variable that appears on the right side of the structural equation to be estimated (this is stage 1); it then replaces the observed data for those endogenous variables by the values calculated from the reduced form, and computes the LS estimator for the resulting equation (this is stage 2). For eqn [1], stage 1 is to compute the LS estimators of the π's in the price eqn [3] of the reduced form; the second stage is to compute $\widehat{p} = \widehat{\pi}_{11} + \widehat{\pi}_{12} y + \widehat{\pi}_{13} w$, substitute this $\widehat{p}$ for p in (1), and compute the LS estimator $\sum q^* \widehat{p}^* / \sum \widehat{p}^{*2}$, which is the 2SLS estimator of β_1. 2SLS is an IV estimator, its instruments are the observed values of the equation's predetermined variables and the reduced-form-calculated values of the endogenous variables from the equation's right side. 2SLS is a *generalized* method of moments (GMOM) estimator (Hansen, 1982). LS and IV are plain MOM estimators.

The k-class estimator (Nagar, 1959) includes as special cases LS, 2SLS, and the limited information maximum likelihood estimator (LIML) (Anderson and Rubin, 1949, 1950). LIML is similar to 2SLS (the two are the same for infinitely large samples), but it has largely been displaced by 2SLS because it requires iterative computations which 2SLS does not, and because it often has a larger variance and sometimes yields outlandish estimates (Kadane, 1971; Theil, 1972).

For an identified structural equation, ILS, IV, LIML, and 2SLS are consistent if the model's explanatory variables are predetermined and the shocks have zero means and constant variances and covariances and are independent across time. An advantage of these methods is that, unlike LS, if applied to an unidentified structural equation they fail to yield estimates.

The Bayesian method of moments (BMOM) method (Zellner, 1998) obtains estimators of linear reduced form and structural equations without making assumptions about the likelihood function of the data. It assumes that the posterior expectations of the shocks given the data are uncorrelated with the predetermined variables, and that the differences between actual and estimated shocks have a covariance matrix of a particular form. Zellner shows how to find optimum BMOM estimators for several different loss functions, including a *precision* loss function which is a weighted sum of squares and cross-products of errors. For this loss function, the optimum BMOM estimator of an identified structural equation belongs to the k-class; it turns out to be LS if the ratio of the sample size to the number of predetermined variables in the model is 2, and it approaches 2SLS in the limit as this ratio grows without limit.

When a structural equation is overidentified, restrictions are placed on the reduced form parameters (such as $\pi_{22}/\pi_{21} = \pi_{32}/\pi_{31}$ in the example, because both ratios must equal β_1), but LS estimators of the reduced form ignore this information. Better estimators of the reduced form, because they use this information, can then be obtained by solving the estimated structure (*see* section 'The Need for Estimation of Parameters').

Estimating a Complete System

If in an identified complete simultaneous equations system the shocks are normally distributed and other suitable conditions are satisfied, an asymptotically efficient but computationally complex method of estimating all the parameters of a complete system is the full information maximum likelihood (FIML) method (Koopmans, 1950; Durbin, 1988). It involves maximizing the joint likelihood function of all the data and parameters, and requires iterative computations. It has largely been displaced by the *three stage least squares* (3SLS) method (Zellner and Theil, 1962), which is also asymptotically efficient but is much easier to compute. 3SLS is an application of the GLS method. 3SLS gets the required information on the shocks' covariances from 2SLS estimates of the shocks; hence the name 3SLS.

Cross-Section vs. Time Series Studies

So far the treatment has concerned time series data, where the observations describe the same country, city, family, firm, etc., at successive periods of time. The same type of analysis is

appropriate for cross-section data, where the observations describe different countries, firms, etc., at a single point of time, with obvious modifications. The analysis has also been extended to panel data, that is, a time series of cross-sections.

The Decline of Simultaneous Equations Models

In recent years the econometric literature has paid diminishing attention to simultaneous equations models and their identifiability. Many modern textbooks give these topics little space, and that only near the end of the book (Davidson and MacKinnon, 1993). Perhaps one reason is that modern computers can handle the estimation of nonlinear models, for which identification criteria are much more complicated and for which lack of identifiability is a much rarer problem.

The Problem of Choosing and Testing a Model

Thus far it has been presumed that the model being estimated is an accurate representation of the real-world process that actually generates the data. This is far from certain; at best it is likely to be only approximately true. Any model has been chosen by someone, perhaps with the aid of economic theory about the maximization of profit or utility, or perhaps because it was suggested by previously observed data. But there is no guarantee that it contains the right variables, or that their endogeneity or exogeneity is correctly stated, or that the correct number of lagged variables has been chosen, or that its equations have the right mathematical form, or that the assumed distribution of its shocks is correct.

One can perform diagnostic tests to see whether the estimated model fits past data well, and whether its calculated past shocks have constant variance and are free of any obvious systematic behavior. But this does not assure that it will do well with future data. In my view, the most stringent and most important test of a model is to expose it to data that were not available when the model was formulated. If it does not describe these data well, it leaves something to be desired. The more new data it can describe well, the more confidence one can have in it. But at any point the best that can be said about a model is that it has done a good job of describing the data that are available thus far.

This article is a revision of the previous edition article by J.P. Forsyth, C.G. Finlay, volume 21, pp. 14116–14121, © 2001, Elsevier Ltd.

Abstract

The central aim of the present article is to review (1) the conceptual basis and rationale guiding the use of single-case designs in experimental and applied contexts and (2) the advantages, disadvantages, and flexible application of the main varieties of single-case design strategies. In so doing, emphasis is placed on the value of a single-case design approach for scientists and practitioners alike, particularly as a means to meet the joint pragmatic goals of prediction and control, and hence scientific understanding and increased accountability.

Basic and more applied branches of behavioral science seek to predict and influence a range of behavioral phenomenon with precision, scope, and depth. In so doing, efforts are made to isolate and control for extraneous sources of variability (i.e., noise), so that prediction and/or influence may be achieved. Methodology is simply a way to address such analytic aims, and depending on the level of analysis one adopts, methods may be applied to address questions based on a collection of observations gleaned from several individuals in a population (i.e., group-based methods) or from each individual case. The latter of these approaches is the focus of single-case methodology (Hayes et al., 1999).

The purpose of this article is to provide a succinct description of a methodological approach well suited for work with single organisms, whether in basic research or applied contexts, and particularly where large N designs or inferential statistics are nonsensical and even inappropriate. This approach, referred to here as *single-case design* (formerly referred to as *single-subject design*) methodology includes several design options involving rigorous and intensive experimental analysis of a single unit, and often replications across several individual cases. No attempt will be made here to describe all available design options or statistical tests, as excellent resources are available on both subjects (see Barlow et al., 2008; Busk and Marascuilo, 1992; Hayes et al., 1999; Huitema, 1986; Iversen, 1991; Kazdin, 2011; Parsonson and Baer, 1992). Rather, the intent is to provide (1) an overview of single-case design methodology and the rationale guiding its use in experimental and applied contexts, (2) a succinct description of the main varieties of single-case designs, including basic guidelines for their application, and (3) to highlight recent trends in the use of such designs.

Single-Case Design: Overview and Rationale

At the core, all scientists ultimately deal with particulars, whether cells, atoms, microbes, or the behavior of organisms. It is from such particulars that the facts of science and generality of findings are derived (Sidman, 1960). This is true whether one aggregates a limited set of observations from a large sample of cases into groups that differ on one or more variables, or situations involving a few cases and a large number of observations of each over time (cf. Hilliard, 1993). The former is characteristic of hypothetico-deductive group design strategies that rely on inferential statistics to support scientific claims, whereas the latter idiographic and inductive approach is characteristic of single-case methodology. As with other research designs, single-case methodology is as much an approach to science as it is a set of methodological rules and procedures for answering scientific and practical questions. As an approach, single-case designs have several distinguishing features.

Subject Matter of Single-Case Designs

Perhaps the most notable feature of single-case methodology is its subject matter and sample characteristics, namely, the intensive study of the behavior of a single (i.e., $N = 1$) unit, such as a person, nonhuman animal, or a classroom (Kratochwill and Levin, 2010). This feature is also a source of great misunderstanding (Furedy, 1999), particularly with regard to the generality and scientific utility of research based on an N of 1. It should be stressed that single-case methodology gets its name not from sample size per se, but rather because the analysis focuses on the behavior of individual units (Perone, 1991), or what Gottman (1973) referred to as *N-of-one-at-a-time* designs. Skinner (1966) described it this way: "… instead of studying a thousand rats for one hour each, or a hundred rats for ten hours each, the investigator is likely to study one rat for a thousand hours" (p. 21); this approach served as the foundation for operant learning (Skinner, 1953, 1957) and, with the increasing popularity of behavior therapy, set the stage for a new approach to treatment development, treatment evaluation, and increased accountability (Barlow et al., 2008).

Though single-case research often involves more than one unit (Cooper et al., 2007; Shadish and Sullivan, 2011), the data are evaluated primarily on a case-by-case basis. The idiographic nature of this methodology is well suited for applied work where practitioners often attempt to influence and change problematic behavior(s) of individual clients (Hayes et al., 1999). Though not a requirement, the inclusion of more than one case helps establish the robustness of observed effects across differentially imposed conditions, individuals,

behaviors, settings, and/or time (Horner et al., 2005). Hence, direct or systematic replication serves to increase confidence in the observed effects and helps establish the reliability and generality of observed relations (Sidman, 1960).

Analytic Aims of Single-Case Designs

As with other experimental design strategies, the fundamental premise driving the use of single-case methodology is to demonstrate control (i.e., influence) via the manipulation of independent variables and analysis of the effects of such variables on behavior (dependent variables). This emphasis on systematic manipulation of independent variables distinguishes single-case designs from other small *N* research such as case reports and case studies, which are often lucidly descriptive, but less controlled and systematic. With few exceptions (see Perone, 1991), the general convention of single-case design is to change one variable at a time and to evaluate such effects on behavior. This *one-variable-at-a-time rule* positions the basic or applied researcher to make clear causal statements about the effects of independent variables compared to a previous state (e.g., naturally occurring behavior during baseline), to compare different independent variables across or within conditions, and only then to evaluate interaction effects produced by two or more independent variables together.

Indeed, single-case methodology is unique in that it typically involves an intensive and rigorous experimental analysis of the behavior (i.e., thinking, emotional responses, overt motor acts) across time, and an equally rigorous attempt to isolate and control extraneous sources of variability (e.g., maturation, history) that may confound and/or mask any effects caused by systematic changes in the independent variable(s) across conditions and time (Sidman, 1960). This point regarding the handling of extraneous sources of variability cannot be overstated. Iversen (1991) and others (Barlow et al., 2008; Sidman, 1960) have noted issues concerning how variability is handled in group design research and single-case methodology. With regard to such issues, Iverson put it this way:

> [in group design research] the fit between theory and observation often is evaluated by means of statistical tests, and variability in data is considered a nuisance rather than an inspiration. By averaging over *N* subjects the variability among the subjects is ignored *N* times. In other words, a data analysis restricted to only the mean generates *N* degrees of ignorance. Single-subject designs are used because the data based on the individual subject are more accurate predictors of that individual's behavior than are data based on an averaging for a group of subjects. (p. 194)

Though the issue of when and how to aggregate data (if at all) is controversial in single-case research (see section Analyzing Outcome Data for a discussion), there is a consensus that variability is to be pinpointed and controlled to the extent possible. This is consistent with the view that variability is imposed and determined from without, and not an intrinsic property of the subject matter under study (Sidman, 1960). Efforts are made deliberately to control such noise so that prediction and control can be achieved with precision and scope.

Measurement Issues of Single-Case Design

Single-case design methodology can also be distinguished by the frequency with which behavior is sampled within conditions and across differentially imposed conditions and time. It is common, for instance, for basic and applied researchers to include hundreds of samples of behavior across time (i.e., hours, days, weeks, sessions) with individual subjects. Yet, a minimum of at least three data points is required to establish level, trend, and variability within a given phase or design element (Hayes et al., 1999). Changes in level (i.e., the mean or median within a condition), trend (i.e., the slope of change), and at times variability (i.e., fluctuations around either the level or trend) from one condition to the next, and particularly changes that are robust, clear, immediate, and stable from behavior observed in a prior condition, help support causal inferences.

Here, stability is a relative term and should not be confused with something that is static or flat. Rather, stability provides a background by which to evaluate the reliability of changes produced by an independent variable across conditions and time. By convention, each condition is often continued until some semblance of stability is observed, at which point another condition is imposed, and behavior is evaluated relative to the previous condition or steady state (cf. Perone, 1991). Such changes, in turn, are continuously evaluated relative to a prior less controlled state (i.e., baseline) or adjacent conditions involving another independent variable. In single-case methodology, such stability can be evaluated within a condition (i.e., from one sample or observation to the next) and across conditions (i.e., changes in level, trend, variability). The pragmatic appeal of such an approach, particularly in applied contexts, rests in allowing the practitioner to evaluate the effectiveness of imposed interventions in real time, and consequently to modify their intervention tactics as the data dictate. Indeed, unlike more formal group-designs that are followed strictly once set in place, single-case methodology is more flexible. It is common for design elements to be added, dropped, and/or modified as the data dictate so as to meet scientific and applied goals. This feature has obvious parallels with how practitioners work with their clients in designing treatment interventions (cf. Hayes et al., 1999).

In sum, all single-case designs focus on individual organisms and aim to predict and influence behavior via (1) repeated sampling and observation, (2) manipulation of one or more independent variables while isolating and controlling sources of extraneous variability to the extent possible, and (3) demonstration of stability within and across levels of imposed independent variables (cf. Perone, 1991). Discussion will now turn to an enumeration of such features in the context of more popular single-case designs.

Varieties of Single-Case Methodology

Most single-case designs can be classified generally as representing two main types: within and between-series designs. Though each will be discussed briefly in turn, it is important to recognize that neither class of design precludes combining elements from the other (e.g., combined-series elements). In

other words, a within-series design may, for some purposes, lead the investigator to add between-series elements and vise versa, including other more complex elements (e.g., interaction effects, changing criterion elements).

Within-Series Designs

The basic logic and structure of within-series designs are simple; namely, to evaluate changes within a series of data points across time on a single measure or set of related measures (cf. Hayes et al., 1999). Stability is judged for each data point relative to other data points that immediately precede and follow it. By convention, such designs include comparisons between a naturally occurring state of behavior (typically referred to as the baseline and denoted by the letter A) and the effects of an imposed manipulation of an independent variable or intervention (denoted by different letters such as B and C). A *simple A–B design* involves sampling naturally occurring behavior (A phase), followed by repeated assessment of responding when the independent variable is introduced (B phase). For example, suppose a researcher wanted to determine the effects of rational-emotive therapy on initiating social interactions for a particular client. If an A–B design were chosen, the rate of initiations prior to treatment would be compared to that following treatment in a manner analogous to popular pre-to-post comparisons in group-outcome research. It should be noted, however, that simple A–B designs are inherently weak in controlling for threats to internal validity (e.g., testing, maturation, history, regression to the mean). *Withdrawal/reversal designs* control for such threats, and hence provide a more convincing case of experimental control.

Withdrawal designs represent a replication of the basic A–B sequence a second time, with the term withdrawal representing the imposed removal of the active treatment or independent variable (i.e., a return to second baseline or A phase). For example, a simple A–B–A sequence allows one to evaluate treatment effects relative to baseline responding. Effects due to treatment should diminish once treatment is withdrawn and the subject or client is returned to an A phase. Other variations on withdrawal designs include B–A–B designs and A–B–A–B–A–B (reversal) designs (see Barlow et al., 2008; Hayes et al., 1999). The A–B–A–B–A–B design provides at least one, or a series, of treatment reinstatement phases (i.e., a return to a second B phase) following withdrawal. Thus, treatment effects should be once again observed after such a switch in phase, providing within-unit replication and contributing to the reliability of the observed effect.

A–B designs and withdrawal/reversal designs are typically used to compare the effects of a finite set of treatment variables to baseline response levels. Data regarding stable response trends are collected across several discrete periods (e.g., time, sessions), wherein the independent variable is either absent (baseline) or present (treatment phase). Phase shifts are data-driven, and response stability determines the next element added to the design; elements that may include other manipulations or treatments either alone (e.g., A–B–A–C–A–B–A) or in combination (e.g., A–B–A–B + C–A–B–A). As the manipulated behavior change is repeatedly demonstrated and replicated across increasing numbers of phase shifts and time, confidence in the role of the independent variable as a cause of such changes increases.

This basic logic of within-series single-case methodology has been expanded in sophisticated and at times complex ways to meet basic and applied purposes. For instance, such designs can be used to test the differential effects of more than one treatment. Other reversal designs (i.e., B–C–B–C) involve the comparison of differential, yet consecutive, treatment interventions across multiple phase shifts. These designs are similar to the above reversals in how control is evaluated, but differ primarily in that baseline phases are not required. Designs are also available that combine features of withdrawal and reversal. For example, A–B–A–B–C–B designs allow one to compare A and B phases to each other (reversal; A–B–A–B), and a second treatment to B (reversal; e.g., B–C–B), or even to evaluate the extent to which behavior tracks a specified behavioral criterion (i.e., changing criterion designs; see Hayes et al., 1999).

Changing criterion designs provides an alternative method for experimentally analyzing behavioral effects without subsequent treatment withdrawal. Criterion is set such that optimal levels given exposure can be met and then systematically increased (or decreased) to instill greater demand on acquiring new repertoires. For example, a child learning to add may be required to calculate four of 10 problems correctly to earn a prize. Once the child successfully and consistently demonstrates this level of responding, the demand increases to 6 of 10 correct problems. Changing criterion designs serves as a medium to demonstrate learning through achieving successive approximations of the end state, and may be one strategy employed when a return to the baseline phase is unlikely (e.g., once acquired, mathematical skills or other behavioral skills are unlikely to revert to a previous baseline state) or when ethical concerns suggest that a return to baseline may be harmful (e.g., reinstating the self-injurious behavior of a child with an autism spectrum disorder).

Between-Series Designs

Between-series designs differ primarily from within-series designs in that data are first grouped and compared by condition, and then by time, whereas the reverse is true for within-series designs. Between-series designs need not contain phases, as evaluation of level, trend, and stability is organized by condition first, but not by time alone (Hayes et al., 1999, p. 176). Designs within this category include *alternating treatment design* and *simultaneous treatment design*. Both allow for the evaluation of multiple (with a minimum of two) treatments concurrently in an individual case.

Alternating treatment designs contain no phases, unlike the previously described within-series designs (Hayes et al., 1999). Rather, concurrent evaluation is made between rapid and largely random alternations of two or more conditions (Barlow and Hayes, 1979). These designs are particularly useful in cases where it would be impractical or unethical to withdraw treatment and in cases where establishing a baseline is unnecessary. Additionally, alternating treatment designs fit well with applied work, as therapists must often routinely target multiple problems concurrently and thus

need to switch rapidly between intervention tactics in the context of therapy.

As with the alternating treatment design, simultaneous treatment designs do not contain phases. In addition, rapid or random alteration of treatment is not required with simultaneous treatment design. What is necessary is that two or more conditions are available simultaneously, with the subject choosing between them. Thus, the simultaneous treatment design is appropriate for situations where one wishes to evaluate the concurrent or simultaneous application of two or more treatments in a single case. While not conducive for evaluating treatment outcome, this particular design is appropriate for evaluating preference or choice (cf. Hayes et al., 1999). For example, multiple reward options could be presented simultaneously (Kratochwill and Levin, 2010). The simultaneous treatment design would not be appropriate for examining the effectiveness of each reward on behavior change, but could be used to evaluate preference for each reward.

Combining Within- and Between-Series Elements

Multiple-baseline designs build upon and integrate the basic logic and structure of within- and between-series elements. The fundamental premise of multiple-baseline designs is to replicate phase change effects systematically in more than one series, with each subsequent uninterrupted series serving as a control condition for the preceding interrupted series. Series can be compared and arranged across behaviors, settings, individuals, or some combination of these (cf. Hayes et al., 1999). Such designs require that the series under consideration be independent (e.g., two functionally distinct behaviors, settings), and that the intervention be administered sequentially beginning with the first series, while others are left uninterrupted as controls. For example, a client might present with three distinct behavior problems all requiring exposure therapy. All behaviors would be monitored during baseline (A phase), and after some semblance of stability is reached the treatment (B phase) would be applied to the first behavior series, while the remaining two behaviors are continuously monitored in an extended baseline. Once changes in the first behavior resulting from treatment achieve stability, the second series would be interrupted and treatment applied, while the first behavior continues in the B phase and the third behavior is monitored in an extended baseline. The procedure followed for the first two series elements is then repeated for the third behavior. This logic can be similarly applied to multiple-baseline designs across individuals or settings (see Barlow et al., 2008; Hall et al., 1970). More complex within-series elements (e.g., A–B–A–B, or B–C–B, or counterbalanced phases such as B–A–B and A–B–A) can be evaluated across behaviors, settings, and individuals.

Note that with multiple-baseline designs the treatment is never withdrawn; rather, it is introduced systematically across a set of dependent variables. Independent variable effects are denoted from how reliably behavior change correlates with the onset of treatment for a particular dependent variable. For such reasons, multiple-baseline designs are quite popular, owing much to their ease of use, strength in ruling out threats to internal validity, built-in replication, and fit with the demands of applied practitioners working in therapy, schools, and institutions. Indeed, such designs can be useful when therapists are working with several clients presenting with similar problems, when clients begin therapy at different times, or in cases where targets for change in therapy occur sequentially.

Recent Trends in the Application of Single-Case Methods

Over 30 journals within psychology and education have recently published single-case design studies (Shadish and Sullivan, 2011) – an encouraging trend compared to the use of such designs over a decade ago (see Forsyth et al., 1999). Yet, single-case methods remain controversial owing, in part, to disagreements regarding proper methodology for examining single-case data, criticisms that single-case designs lack strong methodologies (i.e., lack of randomization), and the need for accountability in applied practice. It is to a discussion of such issues that we now turn.

Analyzing Outcome Data

Historically, visual inspection of plotted data has been the primary method of analyzing single-case data (Parsonson and Baer, 1992), and it was assumed that the researcher-practitioner's focus on control of extraneous causes of error would lead to more Type II errors (i.e., to deny a difference and claim that a variable is not exerting influence over behavior, when it is) compared to more classic Type I errors (i.e., to claim that a variable is exerting influence over behavior, when it is not; cf. Baer, 1977). However, early research suggested that visual inference is unreliable. This is particularly true of datasets based on short series, with a good deal of variability, and autocorrelation (i.e., serial dependence, wherein one observation depends in part on the previous observation; Borckardt et al., 2008), such as that often found in published literature and applied settings (DeProspero and Cohen, 1979; Jones et al., 1978). These and other factors tend to result in inflated Type I errors (Matyas and Greenwood, 1990).

Given possible problems with visual inspection techniques, several calls were made to apply various inferential/randomization statistical approaches to single-case generated data. Though in-depth discussion of these newer methods are beyond the scope of this paper (for reviews see Haardörfer and Gagné, 2010; Manolov et al., 2010), we nonetheless wish to highlight some core concerns emerging from this line of work. First, statistical methods rely on randomization techniques, whereas single-case designs do not (e.g., Haardörfer and Gagné, 2010). Second, such techniques are also impacted by autocorrelation of the data, often resulting in low power and inflated Type I errors (e.g., Borckardt et al., 2008; Haardörfer and Gagné, 2010), particularly when examining short data series (e.g., Manolov et al., 2010). Third, the complexity of some of the proposed analyses may be cumbersome and expensive for practitioners to implement in applied settings. Finally, work on visual inspection techniques suggests that both inter-rater reliability (Hagopian et al., 1997) and accuracy (Fisher et al.,

2003) can be improved through the implementation of training and adherence to structured visual/graphical analysis techniques and correspondence with expert visual analysts. Such improvements in visual inference, coupled with their acceptability, ease of use, and fit with applied practice, make visual/graphical techniques the preferred method when examining single-case data (Haardörfer and Gagné, 2010; Wolery et al., 2010).

Improving Validity

As previously noted, replication of effects across individuals, settings, behaviors, etc. is the traditional strategy used to establish the reliability and generality of inferences gleaned from single-case research designs. Group-based designs, by contrast, tend to employ randomization techniques to improve internal validity. However, randomization need not be exclusive to the domain of hypothetico-deductive group designs. Kratochwill and Levin (2010) have recently provided an excellent introduction to combining both simple and block randomization procedures using single-case methodology. For example, they illustrate implementation of *randomized phase-order designs*, where the sequencing of the A and B phases are randomized using either simple or block randomization for each of the designs presented above. *Randomized phase start-point designs* alter the commencement of each phase, again using either simple or block randomization techniques. In addition, the authors extend both randomized order and start point designs to include replication across units (e.g., multiple individuals, classrooms) and to provide predetermined baseline phases when required.

Instituting randomization techniques will improve the internal validity of single-case designs. However, these advantages come with certain costs (Kratochwill and Levin, 2010). Additional phase changes may be needed to meet desired withdrawal and reversal observations, resulting in increases to time and cost in research settings. Also, perhaps one of the strongest features of single-case designs, particularly in applied settings, is the flexibility offered in allowing the data to guide phase changes and identify new independent variables for manipulation. However, predetermined a priori randomized schedules eliminate such flexibility and may impact the ability to achieve stable behavior levels within a phase. In spite of these limitations, we expect this powerful methodological addition to the scientist-practitioner's arsenal to support and increase the validity of future single-case work.

Accountability and Managed Care

Increasingly, third-party payers are requiring practitioners to demonstrate accountability, that is, to show that what they are doing with their clients is achieving the desired effect (i.e., good outcomes) in a cost-effective and lasting manner. Use of single-case methodology has a place in assisting practitioners in making clinical decisions based on empirical data, monitoring progress and effectiveness of treatment, and in demonstrating accountability to third-party payers and consumers. Further, such methodology, though requiring time and sufficient training to implement properly, is atheoretical and fits nicely with how practitioners from a variety of conceptual schools work routinely with their individual clients (Hayes et al., 1999). Also, single-case designs can be implemented as a method of quickly informing consultants, supervisors, or a treatment team as to the progress and effectiveness of a given intervention (Segool et al., 2007). Thus, there is great potential in single-case methodology for bridging the strained scientist-practitioner gap, and ultimately advancing the science of behavior change and an empirically driven approach to practice and treatment innovation.

Summary and Conclusions

Methodology is a way of knowing. Single-case methodology represents a unique way of knowing that has as its subject matter an experimental analysis of the behavior of individual units. Described here were the assumptions driving this approach and the main varieties of design options available to address basic experimental and applied questions. Perhaps the greatest asset of single-case methodology rests with the flexibility with which such designs can be constructed to meet the joint analytic goals of prediction and control over behavior of individuals. This asset also represents one of the greatest liabilities of such designs in that flexibility requires knowledge of when and how to modify and/or add design elements to achieve analytic goals, and particularly skill in recognizing significant effects, sources, or variability, and when one has demonstrated sufficient levels of prediction and control over the behavior of interest.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Situated Knowledge, Feminist and Science and Technology Studies Perspectives

Charis M Thompson, London School of Economics and Political Science, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, the feminist and science and technology studies roots of situated epistemology are discussed. The idea of combining a commitment to a real world, albeit a constructivist one, with attention to practice and embodiment is assessed. The controversial conferral of agency on nonhuman objects is similarly explicated. Finally, uptake and critique of the notion of situated knowledges is addressed.

The expression 'situated knowledge,' especially in its plural form 'situated knowledges,' is associated with feminist epistemology, feminist philosophy of science, and science and technology studies. The term was introduced by historian of the life sciences and feminist science and technology studies scholar Donna Haraway in her landmark essay *Situated Knowledges: The Science Question in Feminism and the Privilege of Partial Perspective* (Haraway, 1991: 183–201). The essay was a response to feminist philosopher of science Sandra Harding's discussion of the "science question in feminism" (Harding, 1986). In her analysis of the potential of modern science to contribute to the goals of feminism, Harding noted three different accounts of objective knowledge in feminist epistemology: feminist empiricism, feminist standpoint, and feminist postmodernism (Harding, 1986: 24–26). Feminist empiricism attempted to replace more-biased with less-biased science. The feminist standpoint, echoing the Marxist tradition from which it derived, stressed the relevance of the social positioning of the knower to the content of what is known. Feminist postmodernism accentuated the power dynamics underlying the use of the language of objectivity in science. Haraway, taking off from Harding, diagnosed a 'Scylla and Charybdis' of temptations between which feminists attempt to navigate on the question of objectivity: radical constructionism and feminist critical empiricism. As she put it, what feminists wanted from a theory of objectivity was "enforceable, reliable accounts of things not reducible to power moves and agonistic, high status games of rhetoric or to scientistic, positivist arrogance" (Haraway, 1991: 188). Her notion of situated knowledges was her attempt to provide just such a theory of objectivity.

Despite the single author provenance, the term resonated with attempts by other scholars in the history, sociology, and philosophy of science to address similar epistemological tensions. The concept was quickly and fruitfully taken up in science and technology studies and feminist theory, provoking a certain amount of reworking in its turn.

'Situated Knowledge' and Objectivity: Constructed Yet Real

The term 'situated knowledge' derives its theoretical importance from its seemingly oxymoronic character, particularly when applied to knowledge about the natural world. It is common to think of modern scientific knowledge as universal, so that it has the same content no matter who possesses it. It is also almost definitional to hold that objective knowledge is warranted by the fact that it captures reality as it really is, rather than being warranted by the situational circumstances out of which the knowledge was generated or discovered (see Shapin, 1994: 1–8 for discussion of, and citations relevant to, various manifestations of these points). Thus, if the law of gravity enables us to make reliable experimental predictions, it is because there is such a thing as gravity that is adequately captured by our scientific understanding; in short, the truth of the knowledge is its own warrant. It is only in the case of false or superseded knowledge that we typically explain what went wrong by reference to faulty assumptions, sloppy work, ill-calibrated equipment, the *Zeitgeist*, or other aspects of the context of discovery. The idea of 'situated knowledge' contests these supposed concomitants of objective knowledge. It suggests that objective knowledge, even our best scientific knowledge of the natural world, depends on the *partiality* of its material, technical, social, semiotic, and embodied means of being promulgated.

Haraway's notion thus had affinities with other feminist epistemologies, which had noted that facts can differ in their content from one time, place, and knower to another (e.g., Collins, 1989). It also had sympathies in common with sociologists of science and scholars of science and technology studies who have suggested that capturing 'reality as it really is' may be dependent on institutional, technical, and cultural norms (Kuhn (1962/1970)), on practice (Clarke and Fujimura, 1992; Pickering, 1992), and attempts to witness, measure, comprehend, or command assent to it (Latour, 1987; Shapin, 1994; Shapin and Schaffer, 1985). All these scholars shared a search for the theoretical resources to do justice to the embeddedness of science and truth. These challenges to conventional views of objectivity brought situated knowledges into conversation with key debates in the philosophy of science around the theory-ladenness of facts (Hesse, 1980: 63–110). Additionally, the suspicion of transcendent universalism entrained an epistemological and political distrust of clear-cut distinctions between subject and object, and a blurring of the distinction between context and content of knowledge or discovery.

Situated knowledges are as hostile to relativism as they are to realism. Haraway describes relativism as "being nowhere while claiming to be everywhere equally" (Haraway, 1991: 191) and realism as "seeing everything from nowhere" (Haraway, 1991: 189), and conceives of them both as 'god-tricks' promising total, rather than partial, located, and embodied, vision. In contrast to realist or relativist epistemologies, Haraway sees the possibility of sustained and rational objective inquiry in the epistemology of partial perspectives. This requires, she maintains, reclaiming vision as a series of technological and organic embodiments, as and when and where and how vision is actually enabled. This crafting of a feminist epistemology of situated knowledges on the basis of vision and partial perspective is noteworthy. The links in the history of science to militarism, capitalism, colonialism, and male supremacy have been theorized around the masculinist gaze of the powerful but disembodied knower disciplining and subjugating the weak by means of a multitude of technologies of surveillance. Feminists have lamented the privilege granted to the visual as a sure basis of knowledge and bemoaned the sidelining in modernity of what some cast as more feminine and less intrinsically violent ways of knowing involving emotion, voice, touch, and listening (Gilligan, 1982). Haraway was concerned that feminists not cede power to those whose practices they wish critically to engage. It is in this spirit that she grounded her feminist solution in an embrace of science and vision, "the real game in town, the one we must play" (Haraway, 1991: 184).

The Feminist Roots of the Dilemma

A tension between emancipatory empiricism and its associated egalitarian or socialist politics, and feminist postmodern constructionism and its associated identity politics, resonates throughout contemporary Western feminist theory. It is a hallmark of those engaged in feminist philosophical and social studies of science that they seek to resolve one or another version of this tension. One horn of the feminist dilemma, according to Haraway, represents the good feminist reasons to be attracted to radical constructionism. Feminist postmodernists, and analysts of science and technology influenced by semiotics (including Haraway herself), helped develop and often appealed to "a very strong social constructionist argument for *all* forms of knowledge claims" including scientific ones (Akrich and Latour, 1992; Haraway, 1991: 184). This position had the benefit of showing the links between power – such things as status, equipment, rhetorical privilege, funding, and so on – and the production of knowledge and credibility. The downside, from the point of view of feminists interested in arguing for a better world, is that the radical constructionist argument risks rendering all knowledges as fundamentally ideological, with no basis for choosing between more and less just ideas, more and less true versions of reality. As Haraway provocatively expressed it, embracing this temptation seemed to leave no room for "those of us who would still like to talk about *reality* with more confidence than we allow the Christian right's discussion of the Second Coming and their being raptured out of the final destruction of the world" (Haraway, 1991: 185).

The second horn of the dilemma, according to Haraway, involves "holding out for a feminist version of objectivity" through materialism or empiricism (Haraway, 1991: 186). Haraway briefly discusses both Marxist derived feminisms and feminist empiricism. Feminisms with Marxist inspirations are several, and their genealogy can be traced in a number of ways. Feminists have long criticized Marxist humanism for its premise that the self-realization of man is dependent on the domination of nature, and for its account of the historical progression of modes of production that grants no historical agency to domestic and unpaid labor (Hartmann, 1981). Some have responded by developing feminist versions of historical materialism (Hartsock, 1983). Feminist standpoint theorists appropriated the general insight, inherited from both Marxist thought and the sociology of knowledge, that one's social-structural position in society – such things as one's class or relation to the means of production, or one's gender or ethnonational characteristics – determines or affects how and what one knows (Smith, 1990).

Likewise, the idea that some social-structural positions confer epistemological privilege has been widely adopted by standpoint theorists and feminist epistemologists arguing for specifically feminine ways of knowing (Rose, 1983). 'Seeing from below,' that is, from a position of subordination, has commonly been theorized by feminists as the position of epistemological privilege, on the grounds that those with little to gain from internalizing powerful ideologies would be able to see more clearly than those with an interest in reproducing the status quo. In Patricia Hill Collins' version of standpoint theory, for example, these insights are used both to validate the knowledges of the historically disenfranchised and to reverse the hegemonic ranking of knowledge and authority, and claim epistemological privilege for African-American women (Collins, 1989).

Psychoanalytic theory, particularly Anglophone object relations theory, inspired some of the early writings on gender and science (Chodorow, 1978; Keller, 1985). Object relations theory attempted to explain the different relation of women and men to objectivity, abstract thought, and science in modern societies. To account for this difference, the theory posited gender-based differences in the socialization of sons and daughters in Western middle-class heterosexual nuclear families. Boys, according to this theory, are socialized to separate from the primary caregiver who is the mother in this normative family scenario. They thus learn early and well by analogy with their emotional development that relational thinking is inappropriate for them; separating themselves from the object of knowledge, as from the object of love, is good. Girls, on the other hand, are supposedly socialized to be like their primary caregiver, so that they can reproduce mothering when their turn comes. Relationality and connectivity, not abstraction and separation, are the analogous ordering devices of girls' affective and epistemological worlds. As applied to objectivity and scientific knowledge, object relations theory seemed to explain to feminists, without resort to distasteful biological determinisms denying women scientific aptitude, why women were excluded from much of science and technology. It also suggested that there were (at least) two distinct ways of knowing, and that much might have been lost in the violence and separation of masculinist science that could be

restored by a proper valuation of the feminine values of connection and empathy (Harding, 1986; Keller, 1983). Like Marxism, psychoanalytic approaches to objectivity gave feminists a means to show the relevance of one's social position to knowledge. Like feminist empiricism, they encouraged the belief in the possibility of an improved, feminist, objectivity (Harding, 1992).

The feminist canon contains a number of empirical studies that have revealed the negative effects of such things as colonialism and stereotypes about race and gender on the production of reliable science (Fausto-Sterling, 1995; Martin, 1991/1996; Schiebinger, 1989; Traweek, 1988). Evelyn Fox Keller's call for "dynamic objectivity" (Keller, 1985: 115–26) and Sandra Harding's demand for "strong objectivity" (Harding, 1992: 244) are exemplary of the aspirations of theoretical feminist empiricism. These projects seek to prescribe scientific methods capable of generating accounts of the world that would improve upon disembodied, masculinist portrayals of science because they would be alert to the practices of domination and oppression inherent in the creation, dissemination, and possession of knowledge. Feminist empiricism nonetheless remains problematic because of its reliance on the dichotomies of bias vs. objectivity, use vs. misuse, and science vs. pseudoscience. The feminist insight of the "contestability of every layer of the onion of scientific and technological constructions" (Haraway, 1991: 186) flies in the face of leaving these epistemological dichotomies intact.

Subjects, Objects, and Agency

Haraway's notion of situated knowledges problematizes both subject and object. Unlike standpoint theories which attribute epistemological privilege to subjugated knowers, and the sociology of knowledge which attributes espitemological privilege to those in the right structural position vis-à-vis a given mode of production, Haraway attributes privilege to partiality. This shift underscores that "situated knowledge" is more dynamic and hybrid than other epistemologies that take the position of the knower seriously, and involves "mobile positioning" (Haraway, 1991: 192)

In situated knowledges based on embodied vision, neither subjects who experience, nor nature which is known, can be treated as straightforward, pre-theoretical entities, "innocent and waiting outside the violations of language and culture" (Haraway, 1991: 109). Haraway maintains that romanticizing, and thus homogenizing and objectifying, the perfect subjugated subject position is not the solution to the violence inherent in dominant epistemologies. As feminists from developing countries have also insisted, there is no innocent, perfectly subjugated feminist subject position conferring epistemological privilege; all positionings are open to critical reexamination (Mohanty, 1984/1991). Subjectivity is instead performed in and through the materiality of knowledge and practice of many kinds (Butler, 1990: 1–34).

Conversely, the extraordinary range of objects in the physical, natural, social, political, biological, and human sciences about which institutionalized knowledge is produced should not be considered to be passive and inert. Haraway says that situated knowledges require thinking of the world in terms of the "apparatus of bodily production." The world cannot be reduced to a mere resource if subject and object are deeply interconnected. Bodies as objects of knowledge in the world should be thought of as "material-semiotic generative nodes," whose "boundaries materialize in social interaction" (Haraway, 1991: 201). The move to grant agency to material objects places the epistemology of situated knowledges at the center of scholarship in science and technology studies (Callon, 1986; Latour, 1987).

Uptake and Critique

Donna Haraway's essay ranks among the most highly cited essays in science and technology studies and has been anthologized. As stated above, situated knowledges is a provocative and rich methodological metaphor with resonances in many quarters. The dialogue between Harding and Haraway continued after the publication of *Situated Knowledges* (Harding, 1992: 119–163). Her epistemology directly influenced, and in turn was influenced by, the work of sociologists and anthropologists of science (Clarke and Montini, 1993; Rapp, 1999), feminist philosophers of science (Wylie, 1999), and practicing feminist scientists (Barad, 1996). In addition, 'situated knowledges' was used as a standard technical term of the field by more junior scholars, including many of Haraway's former students. Over time, the idea of situated knowledges has appeared in more domains, including scholarship on education and the environment (e.g., Lang, 2011; Calvert, 2012).

Critics of situated knowledges have been few. Timothy Lenoir has pointed out that many of the epistemological ideas behind Haraway's situated knowledges are found not only in other major strands of science and technology studies, but also in the work of continental philosophers such as Nietzsche. He likewise critiqued the idea of situated knowledges for its dependence on the apparatus of semiotics (Lenoir, 1999: 290–301). Historian Londa Schiebinger, in her book summarizing the effects of a generation of feminist scholarship on the practice of science, placed Haraway's situated knowledges together with Harding's strong objectivity as attempts to integrate social context into scientific analysis (Schiebinger, 1999). Implicit critiques have been leveled against the limitations of the idea of being situated, for example, in the development of De Laet's and Mol's mobile epistemology (De Laet and Mol, 2000). Sheila Jasanoff and her colleagues argued for bringing differently spatialized entities such as the nation, the local, and the global into the epistemology of science and technology studies, while retaining the insights gained by paying attention to practice, vision, and measurement. These critiques stand more as continuing conversations with, than rebuttals of situated knowledges, however. Scholars and former Haraway students have continued to work with situated knowledges and its limits (e.g., Charis Thompson's (2014) loss of her field-site, and Kim TallBear's (2013) idea of 'rootedness' and 'routedness'). Overall, the idea of situated knowledges remains central to feminist epistemology and science studies and to attempts to understand the role of modern science in society.

This article is a revision of the previous edition article by A. Renkl, volume 21, pp. 14133–14137, © 2001, Elsevier Ltd.

Abstract

This article outlines the origins and meaning initially ascribed to 'situated learning,' drawing out the distinction between learning activity that takes place *in situ* and the epistemologically different idea that knowledge itself can be understood as situated. It details some instructional forms that have dominated the situated learning literature over recent years and which show how those original frames have become expanded and potentially distorted in application. It considers some critiques of situated learning. The focus then shifts to ways in which theorizing learning outside the classroom is developing more generally.

Situated learning refers to the notion that learning is affected by situation; and hence must be of relevance to anyone wishing to think about teaching and learning in and outside of classrooms. While this may seem straightforward and common sense, such a literal definition hides a number of complications, each of which has potential pedagogical implications.

This article first of all outlines the origins and meaning initially ascribed to situated learning. It then details some particular contexts that have dominated the situated learning literature over recent years and which show how those original frames have become expanded and potentially distorted in their application. It considers some critiques of situated learning. The focus then shifts to ways in which theorizing learning outside the classroom is developing more generally.

Learning *In situ*

Dickens' classic novel, *Hard Times* (Dickens, 1854: 1), begins with Mr Gradgrind's declaration that

> … what I want is, Facts. Teach these boys and girls nothing but Facts. Facts alone are wanted in life. Plant nothing else, and root out everything else. You can only form the minds of reasoning animals upon Facts: nothing else will ever be of any service to them.

Such an assertion reflects an assumption about learning as a process of acquisition. While Gradgrind wanted facts, a more contemporary version might also add skills and understanding as well as attitudes and beliefs. However, as Sfard (1998) points out, as long as theories "focus on the 'development of concepts' and 'acquisition of knowledge,' they implicitly agree that this process can be conceptualized in terms of the *acquisition metaphor*" (6, emphasis in original). Involved in this metaphor are many related assumptions about learning, and hence about teaching, including that: learning takes place through and in the mind; context stimulates learning, but is separate from it – means and ends are separate; knowledge, carried in the mind, is transferable; and expertise is a measure of quantity, rather than quality. Furthermore, there are a number of theories about how such acquisition takes place; Gradgrind's passive reception (the image of the empty vessel waiting to be filled comes from this same passage) has been superseded by notions of concept construction, with associated claims about readiness (Piaget, 1952) and then co-construction in a social arena (e.g., Vygotsky and Cole, 1978). Moreover, knowledge can also be of different forms: explicit, propositional, public, or hard; tacit, implicit, private, or soft (see Hildreth and Kimble (2002) and Eraut (2000) for useful reviews of these terms).

In all these ways of conceiving of learning, the individual is the unit of analysis. That is, whatever the mode by which learning takes place, the learning itself resides within and is the possession of the individual. In this individualized conception of learning, the role of situation is part of the *means* by which learning takes place. From this perspective its role is to alter the stimulus through, or mechanism by, which individuals come to acquire new knowledge – the practice of learning. Coupling this with the notion that the context in which something is learned, shapes the *form* of resultant learning and is therefore more, or less, useful in different situations, leads to the common idea that much of what is learned in formal settings (schools, universities, etc.) is 'inert' (Renkl et al., 1996) and/or learned inefficiently. Instead, it is argued, learning should take place in contexts that reflect 'real' situations, either replicated in the formal setting or by taking learners outside so that learning is both stimulated through experiences with which to construct meaning and developed in forms that 'fit' future use.

Learning *as Situated*

In the 1980s, a number of studies began to question this acquisition metaphor of learning and point to problems with the whole idea of context. Largely, these were prompted by observations of learning taking place in nonformal situations. Jean Lave's work with apprentice tailors in Liberia and with supermarket shoppers' mathematics perhaps most famously (though by no means solely – see also, for example, Rogoff, 1990; Nunes et al., 1993) led to the development of the idea of cognition in practice (Lave, 1988; Chaiklin and Lave, 1996) and subsequently to learning situated in practice within communities (Lave and Wenger, 1991). As Lave (1996: 5) notes,

> It is difficult when looking at everyday activity … to avoid the conclusion that learning is ubiquitous in ongoing activity. Situated activity always involves changes in knowledge and action … and "changes in knowledge and action" are what we mean by "learning."

Whereas previous research into cognition had always focused on individuals, albeit acting in social settings, this research refocused on the relationships between people, and between people and artifacts, in social activity. The unit of analysis here is no longer the individual, but the group and the activity undertaken within it; attention is fixed on learning that takes place through social 'community' practice; and learning itself – *what* is learned – becomes a question of how the person changes, not what is acquired, so that questions of identity and change become central to understanding learning. Contrary to learning as acquisition, Sfard (1998) refers here to the (metaphorical) idea of learning as *participation*.

This alternative, situated, perspective on learning involves an important distinction from the notion above. Whereas 'situated learning,' in the sense of learning (as acquisition) taking place *in situ*, has implications for the *means* by which learning takes place, Lave's use of the phrase implies an *epistemological* shift. In this version of 'learning being situated,' the meaning is that knowledge is no longer seen as a possession of the individual to be carried around, unpacked, and made use of across situations, but that meaning itself is 'held' in the relationships between people, artifacts, and activity. In this sense situated learning implies a change not just in the means of learning, but in its *ends* too; so that

> 'cognition' observed in everyday practice is distributed – stretched over, not divided among – mind, body, activity and culturally organized settings (which include other actors).
> (Lave, 1988: 1)

Learning from this perspective is 'embodied'; that is built into the activity of people's practice in social contexts so that it makes more sense to talk about 'knowing' as a process of activity and to situated *meaning*, than knowledge as an object.

It is perhaps worth noting at this stage that defining learning in terms of acquisition or participation reflects an attempt to make sense of something too complex to understand in any single way. In this sense, these theorizations are perhaps best seen as heuristic devices for making sense of how learning works, not claims that they model 'how learning is' (Lea, 2005). The participatory metaphor works at the level of social and cultural interaction. The acquisitive metaphor zooms in on the individual. Continue to zoom in and you come to neuroscience which, "broadly defined investigates the process by which the brain learns and remembers" (Goswami, 2004: 1); zoom out and you reach the sociological level, which aims to make sense of human activity in broad social contexts. All offer different ways to make sense of learning.

The situated view of learning, which has emerged from the focus on interaction of individuals in social practice, has been developed in a number of ways, the best known of which are probably Cultural Historical Activity Theory (CHAT) and Communities of Practice (CoP). The former takes its shape from Engeström who built on the Vygotskian idea of subjects' understanding of objects being mediated by artifacts by setting it in the wider social and historical context of community with its associated rules and divisions of labor. The resulting CHAT model (see, for example, Engeström et al., 1999) aims to focus attention on the whole system of activity within which people act, and the tensions and contradictions that drive such activity. The latter, CoP, comes from Lave and Wenger (1991; also Wenger, 1998) and focuses on the notion of practice in social communities and on learning as the movement from 'legitimate peripheral participation' to more central, expertise. Learning is again seen as change, this time in terms of identity (becoming), community (belonging), meaning (experiencing), and practice (doing) (Wenger, 1998: 5).

It should be evident from the above that the term 'situated learning' represents a contested concept complicated by the notion that 'situated' can refer to both the physical sense of place and authenticity and to the epistemological notion that knowledge itself can be understood to reside in and across people and artifacts in context. In the following sections, different instructional forms associated with theories of situatedness are discussed to illustrate how the concept has expanded and potentially been distorted in practice and we try, as best we can, to distinguish between those that relate to acquisitional learning *in situ* and/or to theories in which meaning itself is situated.

Learning as Apprenticeship

Brown et al. (1989) developed the instructional cognitive apprenticeship model in response to their belief that learning was social rather than individual and that abstract learning was of limited use for real-world contexts as it could not easily be applied. It was intended to make more visible the strategies and processes of an apprenticeship form of learning through authentic problems in school settings. Both expert and learners think out loud so that different ways of approaching the problem are available to all. Learners tackle tasks of increasing challenge supported by an 'expert' and gradually take on more responsibility, moving from legitimate peripheral participation to full participation (Lave and Wenger, 1991). Despite this articulated aspect, the learning retains tacit elements that characterize it as a form of enculturation into ways of doing and behaving rather than as ways of knowing. In Wenger's (1998: 5) terms, it is about understanding learning in terms of belonging, becoming, meaning, and experience. Sadler et al. (2010) reviewed 53 studies of scientific research apprenticeship schemes for secondary and postschool students and suggested that, while broadly successful, attention was needed to the desired outcomes, length of apprenticeship and motivational engagement of those taking part. A new wave of research on this form of situated learning may be stimulated by the UK government's recent revival of apprenticeship as a means of learning through the National Apprenticeship Scheme (2008), after years of declining apprenticeships, which fell from 240 000 in the mid-1960s to 53 000 by 1990 alongside rising post-16 participation in full-time education.

Place-Based Learning

A development in the relationship between situation and learning over the last decade has been in the field of place-based learning. As a challenge to content-driven, instructive educational approaches there has been a push within the environmental education sector for 'hands-on' experiential learning experiences that involve the co-creation of positive environmental and social change. This community interpretation of place-based education is more dominant in the US with proponents such as Gruenewald (2003) and Seaman (2007). The notion of situated learning is employed to describe changes that occur in projects *in situ*, for example, around watershed restoration, community forestry, and other civic ecology activities (Tidball and Krasny, 2007). Within these projects adults act as facilitators of learning and as experienced practitioners in a civic ecology community rather than as instructors. In this way, students develop the capacity to play a meaningful role in shaping their own future and that of their larger community.

In a transnational example of the role of situated learning in civic education, Hoskins et al. (2012) reanalyzed data from the 1999 IEA CIVED transnational study to examine how young people learn positive attitudes toward participation in and knowledge and skills of democracy. They found that learning through social participation, both inside and outside school, and in particular through meaning-making activities shows a strong positive relationship with citizenship knowledge, skills, and dispositions across a wide range of countries. This study is unusual in that it worked with situated learning theory and large-scale, quantitative data.

Turning to science learning through community participation, Fusco (2001) describes a 9-month science project geared toward youth between 12 and 16 years of age, which provided opportunities to participate in real-world activities as they turned a disused community garden into a useable space that included a playground, garden clubhouse, penny store, jungle gym, sandbox, and stage. The usefulness of the 'science' learned was questioned by Fusco (2001), who argues that these opportunities alone do not guarantee that young people will find school (or science) more relevant or be less alienated from school and society – for reasons we outline later in this article. However, a particular turning point for the project was when the young people involved in the project started to realize that the project was not 'fake'; "that they were not simply researching ideas (talking about science) but enacting them (doing science)"(868).

Different aspects of what it might mean to create CoP are considered by Boyer and Roth (2006) who describe their eelgrass research project from a situated learning perspective. They point out that different processes unfold concurrently; people of different ages engage in different actions and participate in different ways with multiple orientations rather than a single teacher, and the setting is both materially and socially heterogeneous and complex in comparison with a classroom setting. Such informal settings, they argue, "therefore provide opportunities to expand forms of participation that are less available in more structured school settings" (1030). A similar claim of expansion of learning opportunities is reported by Nadelson and Jordan (2012) who suggest that field trips as a form of situated learning increase students' interest and knowledge. Placing learning in context, they argue, leads students to become motivated and engaged and are therefore likely to generate greater subject matter interest.

Aguilar and Krasny (2011) applied the CoP theoretical framework to environmental education in their study of learning in after-school environmental education programs for Hispanic youth in the US. They suggest that this framing helps conceptualize the joint enterprise, mutual engagement, and shared repertoire of behavior that characterize some environmental education. It was also found to be useful in identifying and describing learning as bringing about changes in identity formation as a result of participation in the programs.

Border crossing between home and school communities is increasingly seen as a way to engage young people not succeeding at school. For example, Faircloth (2012) demonstrates in two studies how students negotiated an engaged identity-in-practice in the classroom. She employs the concept of cultural modeling derived from Lee (2007) to bridge the differences between school-based expectations and students' funds of knowledge by blending the 'authentic' and 'academic' lives of students. Gutiérrez and colleagues (Gutiérrez, 2008; Gutiérrez and Larson, 2007) defined this as 'third space'; the traditional expectations of schooling are interwoven with the informal identities that students value, which are derived from community, culture, family, and interests and which frequently receive less recognition in school. She suggests that this approach allows students to develop what she refers to as 'hybrid identities,' where personal values enmesh with school expectations. This study illustrates a potential critique of situated learning as a vehicle for enacting social change. The warrant for legitimacy of the practices of any community is a key factor and CoP may exclude as well as allow members to adopt more central positions. Wenger (1998) deals with this through reference to 'negotiability' within 'economies of meaning' to illustrate that communities are not neutral places but invested with power derived from wider social structures.

Problem-Based Learning

Problem-based learning is also associated with situated learning in response to a concern that school learning is divorced from practical utility for everyday living. This is a strong theme in the literature on situated learning linked to the authenticity of the situation of learning. Greeno (1998) and the Middle School Mathematics Through Applications Project Group, Treffers and Beishuizen (1999) in the Realistic Math Education Project in the Netherlands have used real-world contexts for mathematical problems. As in Collins et al. (1989) model, a key aspect is that the mathematical reasoning within design activities, which is often tacit, is made explicit and supported by conceptual mathematics lessons to scaffold the mathematical understanding needed for the practical tasks. Pratt (2011) suggests that this interlacing of the conceptual and practical is necessary for disciplinary competence in essentially highly abstract subjects such as math, but also recognizes that the world of abstract mathematics is, itself, a legitimate 'situation'; math may legitimately be done for its own sake to develop new mathematical ideas.

The importance of foundational subject knowledge was also a factor in a study of cognitive and motivational effects of

learning *in situ* in secondary schools for typically low-performing pupils (Hauptschule) in Germany. Thiel and Ulber (2004) suggested that deficits in problem solving might be due to pupils lacking well-organized subject knowledge, learning strategies and metacognitive skills so that processing of new information, self-evaluation of the learning process, and the vertical transfer of knowledge necessary for the problem solving were hampered. They concluded that more time and scaffolding would be needed for learning *in situ* to be effective. Yet an earlier study by Ulber (2003) had found that pupils with the poorest preconditions were most favorably affected by a situated approach, but speculated that this might be attributable to them attracting more attention from teachers rather than the community of practice per se. These apparent anomalies in studies indicate that the nature of the relationships within a learning community is fundamental to how successful the learning generated in communities may be. Bennett et al. (2005: 9) conducted a systematic review of context-based approaches in secondary science, which yielded only five studies. They cautiously suggested "context-based approaches provide an effective way to interest and motivate pupils in their science lessons."

Virtual CoP

Over the last decade, problem-based learning as a form of situated learning has particularly been adopted by virtual learning developers. The increasing use of technologies by spatially dispersed communities and by those who physically meet has been studied by Wenger et al. (2005), who concluded that virtual communities performed much the same role through communication tools that include instant messaging, whiteboard and video links, e-mailing, discussion boards, wikis, tweets, and blogs that serve to share and organize community knowing.

In contrast to place-sensitive contexts, there has been a shift in understanding from the notion of learning *in situ* in physical space and real time to the use of situated learning in a virtual context. It is debatable whether significant aspects of learning *in situ* may be lost when the concept is applied to a virtual environment; the physicality of the situation is lost and the individual is no longer exposed to the external dynamic and changing nature of the situation. For example, in the eelgrass mapping project, participants in the project had the opportunity for *impromptu* conversations with passersby, were very much aware of the rising tide and the eelgrass (more-than-human aspects of relationality, which we discuss in a later section), and had the opportunity to go off-task (at least the task as dictated by the teacher). The last point is important; there is space and freedom for learning to emerge in unanticipated ways. This represents a tension in terms of the notion of learning as movement from the periphery to central expertise and refers us back to the idea that such communities are inevitably shaped by wider discourses of power and legitimacy. Additional learning events occurred beyond the stated aims and objectives of the projects. An effective side of learning could be argued to be a significant aspect of learning *in situ*, including a sense of well-being that one gains from working with others or the challenges of maintaining positive relationships within their community. Yet Gee (2008: 35–36) argues, however, that this is not lost in the virtual world and that games still engage the emotions, while Garrison et al. (2000) discuss the need to move beyond cognitive presence in online education to also consider social and teaching presence.

Distance Education

Herrington et al. (2006) claim that the design of online courses can be based on the concepts of situated learning and authentic learning. They suggest that successful distance education should be based upon complex and sustained scenarios (authentic task design), which involve students solving problems in realistic situations "resembling the contexts where the knowledge they are learning will eventually be applied" (3). Yet, despite widespread signaling of situated learning and CoP as theoretical underpinning for virtual learning environments, knowledge may still be viewed as something that may be acquired rather than co-constructed ways of knowing. For example, Campanella et al. (2008) state that

> New technologies can effectively contribute to a movement away from the duplication of traditional instructional methods, both in the classroom and at a distance, toward a more resource-based approach to instruction that no longer emphasizes the teacher as the main source of knowledge. (605)

Furthermore, as we have suggested before, what constitutes 'authenticity' is contested. Generally, it refers to the ordinary practices within the cultural context, so is related to what the norms and expectations are in that setting, and how far the tasks that students are asked to perform align with that. However, work done in school (or any other formal setting) is authentic to that context – i.e., it is 'authentically' schoolwork – and this leads to a related problem of defining the community that learners are central *to*. Formal education is a social practice in its own right and therefore learners' main focus is often on being central (i.e., successful) students, not necessarily central to the 'authentic' context of the problem (see, for example, Pratt and Back (2009) and comments below).

For Hung and Chen (2001), 'situatedness' is inherent in e-learning through its 'anywhere and anytime' access. Working from a situated learning perspective, they set out some key features that characterize e-learning environments as 'situated learning' in their view:

- Web-based so that learners can access the learning environment in their embedded and situated contexts – anywhere and anytime
- portable so that they can be used in context
- focused on tasks and projects, thus enabling learning through doing and reflecting-in-action
- focused on depth over breadth, thus enabling learners to analyze communicative 'speech acts'
- create interdependencies between individuals where novices need more capable peers, thus capitalizing on the zone of proximal development and the diverse expertise within the community
- personalized with tasks that are meaningful to the learner in their context and personalized strategies and content by tracking the learner's history, profile, and progress. (8)

However, the relational aspects of learning in a CoP and movement from the periphery to the center are less clearly delineated by them. Recent advances in Web 2.0 technologies for social networking may be increasing relational capacities in e-learning contexts, which Amin and Roberts (2008) suggest offer virtual spaces that are as productive as actual physical proximity.

Game-Based Learning

Technology has also enabled the creation of near real-life virtual worlds, which give players the feeling of living and assuming a role in a real situation, allowing them to communicate, interact, and cooperate with others *in situ* (Shang et al., 2006). Game-based learning and simulations are increasingly used in educational contexts, building on theories of situated learning, experiential learning, and activity theory and, it is argued, "bring at least some of the benefits of situated learning into the conventional classroom setting" (Lunce, 2006: 40). Educational simulations are seen as providing a method for students to check their understanding of the real world by modeling the structure and dynamics of a conceptual system or a real environment.

Herrington and Kervin (2007) suggest that situated learning concepts underpin the design of many educational computer games, including:

- *Authentic context*: A sustained and complex learning environment that reflects the way the knowledge will ultimately be used and allows sustained exploration because problems are ill-defined, so that students have to *find* as well as *solve* them (Young, 1993).
- *Expert* performance: As in learning through apprenticeship, access to such expert thinking and performances allows students to observe the task before it is attempted.
- *Multiple roles and perspectives*: Affords students' opportunities to investigate multiple ideas, roles, and perspectives.
- *Reflection*: Affords students the opportunity to reflect upon a broad base of knowledge to solve problems, and to predict, hypothesize, and experiment to produce solutions.
- *Collaboration and articulation*: Students work in small groups or pairs and talk about their progress as they go about the task.
- *Coaching and scaffolding*: The teacher coaches and scaffolds rather than instructs.
- *Integrated authentic testing*: Assessment is integrated with the activity rather than a separate test being set.

While these draw on situated learning theory, in common with many applications of the term, the implicit conceptualization of knowledge is acquisitional.

Some Critiques of Situated Learning

As might be apparent from the comments and studies above, many of the examples of situated learning as the term is now used in education retain an individual notion of learning. Lang and Canning (2010) analyzed citations of the term in educational research and argue that despite widespread citation, most are tokenistic and few studies build cumulatively upon the theory. They attribute this as due potentially to two factors: that it offers a tool for thinking rather than the basis for empirical inquiry and that it has an effective 'value-based appeal' (299) for professionals to counterbalance behaviorist and self-directed learning theoretical approaches. If, as we suggest, it is used as one lens among others, its usefulness as a tool for thinking is clear.

Edwards (2005) argues for a relational turn that acknowledges the 'collective competence of a community' and the nature of relationships across which that stretches. She recognizes that learning is constrained and/or afforded (Gibson, 1979) by the system of activity within which individuals work. Analysis of systems that frame the community in which learning is coconstructed have increasingly drawn on Engeström et al.'s CHAT to make such relationships more visible (e.g., Daniels et al., 2007; Williams et al., 2007). Indeed, Engeström and Sannino (2010) argue that expansive learning drawing on activity theory is able to look both outward to the interconnectivity of multiple activity systems and inwards to look at the impacts of subjectivity, embodiment, and affect. Hodkinson et al. (2007: 425) suggest that "the learning of individuals can be understood as a process of becoming, through participation in several different learning cultures over time" and, we would add, places.

Gibson's (1979) theory of affordances refers to the impact of the environment on behavior through perceptions and interaction with what is possible within that context. Apart from physical possibilities, ways of behaving are also constrained by the cultural context as knowledge is co-produced by the learner and the situation in the context of a culture or society, so the position of the learner within the culture is an important factor. Therefore teachers need to respect the knowledge communities from which learners come in order to provide bridging capital that will enable them to access alternative cultural capital (Putnam, 2000). Anderson et al. (1996) argue that while Brazilian street sellers, who correctly calculate the cost of items that they sell in the streets, are unable to answer similar questions at school, it does not mean that arithmetic procedures taught in the classroom cannot be used by shopkeepers, pointing to other apparent examples of 'transfer' of learning such as reading in different contexts. Such tensions are not always fully accounted for in papers drawing on situated learning theory.

Furthermore Miller and Zuengler (2011) argue that not all situated learning may work to the good but may lead to reinforcement of hegemonies in classrooms. They cite their study of English language learners in a high school sheltered civics class and how participation of nonproficient English speakers augmented the linguistic capital of students with stronger English language skills. They argue that resistance to participation may actually work to expose how mainstream practices acquire implicit legitimation that needs to be challenged in diverse societies. As Lave and Wenger themselves (1991: 108–109) comment, "the purpose [of communities of practice] is not to learn *from* talk as a substitute for legitimate peripheral participation; it is to learn *to* talk as a key to legitimate peripheral participation." Thus learning that is regarded as situated must include room for the voice of those at the periphery. Power relationships may limit the extent that participation is possible. Tennant (1997) suggests, "In their

eagerness to debunk testing, formal education and formal accreditation, they do not analyze how their omission [of questions about wider social structures shaping affordances for different people] affects power relations, access, public knowledge and public accountability" (79). Social capital gained in such CoP may differentially exclude members. As an example of an inclusive community, Rogoff, Turkanis, and Bartlett studied how teachers, students, and parents co-developed a school curriculum and pedagogy in a school in Salt Lake City, noting that they prioritized 'instruction that builds on children's interests in a collaborative way' including them in planning learning activities and recognizing that "parents and teachers not only foster children's learning but also learn from their own involvement with children" (Rogoff et al., 2001: 3).

What this demonstrates in part is the potential danger of seeing 'situated learning' as a pedagogical recipe – that is, as a model of how learning can (even should) be developed. However, the use of a situated lens with which to consider learning in different contexts is perhaps more likely to support the exposure of these kinds of inequalities. As we have noted above, such awareness of relationships within systems may be made more apparent through CHAT analyses (Williams et al., 2007).

The question also arises about whether school learning should be 'judged' in terms outside its own context. Sherman (2004) maintains that school science is often unfairly criticized as being a pale imitation of professional science, but she contends it should instead be considered in its own right as a disciplinary exposition of scientific principles and skills rather than a means of creating mini scientists. Jurdak (2006) contends that situated problem solving may lead to an appreciation of both the power and limitations of using mathematics in the real world if the authenticity of the problem tasks is balanced with the mathematical requirements of the curriculum. Both these studies emphasize the wider structural framing of CoPs and the consequent limitations on flexibility within them. Wenger's (1998) original criteria were clear that CoPs arise through collective interest of a community around something that matters to people; this condition of common interest and shared goals may sometimes get overlooked in pedagogical structures that are intended to create (or impose) a learning community. Fueling motivation to participate through interest may present problems perhaps when the agenda for learning is set elsewhere.

A tension also exists between the particular knowing in a community related to specific tasks and a general understanding of ways of working together. Anderson et al. (1996) suggest that transfer can and does occur between learning tasks and is related to the amount of practice and the degree of congruence with other learning. They argue moreover that complex problems do not necessarily lead to better learning as sometimes tasks broken down and addressed in their constituent parts may be more easily tackled, especially by those who find school learning more difficult (see, for example, Forest School pedagogy, which breaks tasks into small steps (Knight, 2010; Maynard, 2007)). On the other hand, Ulber's study (2003) suggests that a gestalt approach may be more appropriate for low-performing students. It is important to bear in mind, as we stated earlier, that situated learning theory is best thought of as a way of looking at learning not a recipe for how learning should happen. Many proponents of situated learning would not claim that group learning is always productive or that individual practice cannot contribute to becoming a more successful participant in social practices, but it does suggest that context and purpose should be considered when planning learning and diverse aims for learning are best supported by a diversity of learning situations (Waite and Pratt, 2011).

Furthermore, one of the side effects of stable CoP is reification (Wenger, 1998: 58) so that ways of doing things become rules and documented procedures, thus the community of a school becomes a less fluid context for certain sorts of learning that are not regarded as legitimate within it. This effect may be compounded by assessment practices that focus on individual rather than group achievements. Most assessment practices in Western societies are geared toward individual attainment and fail to take account of cooperative learning within a standards-driven educational climate, let alone the notion that learning itself can be thought of as distributed across individuals and artifacts. Thus learning, when thought of as socially situated, may be difficult to recognize and credit within the prevalent assessment systems that treat knowledge as a thing that can be owned in order to gain advantage over competitors.

Theorizing Learning Outside the Classroom beyond Situated Learning

This article has looked at situated learning as one theory (among others) that may help to make sense of learning in communities in and out of school. It is essentially a relational view of learning and we have noted how relations between members of communities co-construct understanding through apprenticeship, problem solving, and shared interests. Since its inception, there has been a divergence in the evolution of the concept of situated learning stemming from its interpretation as learning *in situ*, which supports the business of using place, problems, and groups to site learning in legitimate and authentic situations, and learning as situated, which encourages educationalists to think about knowing as nonindividual and context-bound. This divergence leads to some interesting debate about the validity of the virtual for CoP and what authenticity might mean. In this and much existing research and practice that draws on situated learning theory, the relational is read as inherently social, between people.

In the place-based strand or learning *in situ*, the situation (or place) itself is understood as holding a set of expectations or norms of practice and contributing to what can be learned there (see, for example, Massey, 2005). Waite (2013) suggests that scope for ways of being and becoming may be constrained by the cultural density of places, so that schools, for example, that have strongly established norms of practice tend to lead to the reproduction of those practices. Outside the classroom, more ambiguous spaces, where the cultural density of norms and practices is lighter, may afford a greater range of creative and less predictable learning opportunities. In addition, places that have stronger cultural densities associated with other CoP such as students' own home community or a community of

scientists or artists may elicit different opportunities for change and learning (see also Gutiérrez, 2008).

A further line of theory and research that is developing from place-based understandings shifts away from an anthropocentric social focus to include the more-than-human in relational aspects of situated learning theory (Wattchow and Brown, 2011). Critical posthumanist thinking extends the idea of significant members of communities and participation to the more-than-human world (Haraway, 2008). Recognition that human beings are not alone in the world promotes an ecological perspective to learning. The acknowledgment that the more-than-human world has much to teach us is an important new direction in the idea of situated learning for the future of our world.

Implications for Learning Inside and Outside the Classroom

From the acquisitive perspective, spatial connotation of learning *in situ* leads to a focus on the ways in which learning in different 'places' can shape knowledge (as acquisition). This might be greater in efficiency (through motivation, enthusiasm, etc.) or the production of forms of learning that 'fit' the context in which learners might then use it, making learning more 'accessible' and 'fit for purpose.' Taking young learners out to a pond to study frogs will stimulate their learning, and provide access to experiences that they would not otherwise get (many of which might be tacit and embodied) and make it more likely that knowledge is developed in forms that are not 'inert' (Renkl et al., 1996) but are more likely to be usable in the future. In this sense, the hope is that they learn 'better' or 'more' than if they had studied the 'same' knowledge about frogs from a book, including acquiring experiences that would not have been accessible to them (such as feelings, smells, etc.), which form part of an effective development and upon which they can draw in the future (Somerville, 2007).

From the participatory perspective, situation demands a focus on the social activity involved with the connotation that knowledge itself is distributed across the context in which the activity takes place. What learners come to know about frogs is not the same knowledge but learned 'better'; it is a completely different form of 'knowing frogs' (Waite and Pratt, 2011).

The implications of these views of situated learning are numerous, but one or two stand out. Firstly, they raise questions about the nature of learning in different contexts – and hence about problem-based, work-based, place-based, and virtual learning. If it is just a matter of place, and/or task, then these should lead to learning that is different from traditional classrooms; but if the focus is on activity – the practices in which learners and teachers are engaged – then what might matter more is not the place in which learning happens, but the forms of engagement that teachers and learners adopt and the relationships between them. Taking children to a park (Waite and Pratt, 2011) or youngsters to a museum (Peacock and Pratt, 2011) may not change learning significantly if the teachers bring their school relationships with them.

Secondly, if, as suggested earlier, schooling can be seen as a social practice in its own right, learning in alternative situations may not be helpful for schooling if the latter does not offer the same social relationships as the alternative. The much maligned notion of 'teaching to the test' becomes a problem only because of the nature of the test, which represents a very particular socially constructed form of (school) activity. Though space does not allow us to explore this, the implications here are far reaching given the techno-rational version of schooling prevalent at the time of our writing.

Situational Judgment Test

Filip Lievens and Britt De Soete, Ghent University, Ghent, Belgium

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, we give an overview of situational judgment tests (SJTs) as selection instruments. Their history, basic characteristics, and development are presented. The available research evidence regarding their reliability, construct-related validity, criterion-related validity, incremental validity, subgroup differences, and test-taker perceptions is also reviewed. As a general conclusion, the increasing popularity of SJTs in personnel selection seems to be accredited to their potential to capture a variety of constructs and for different purposes. Additionally, SJTs are able to predict several job-related and/or academic criteria while at the same time offering prospects permitting to select for diversity.

History and Definition

During World War II, military selection psychologists were in need of a tool to select competent soldiers to join the armed forces. They developed a job test that consisted of detailed and realistic descriptions of challenging military situations. All descriptions were situations that armed forces were likely to encounter while on the job. After reading each situation, recruits were presented with several potential reactions to the given threat or challenge and they were asked which reaction they considered the most effective response (Northrop, 1989). The instrument turned out to be a success. On the one hand, it gave a realistic job preview of what was to come, thereby discouraging recruits with an unfavorable person–organization fit and lowering attrition rates for the army. On the other hand, the tool enabled to measure recruits' judgment skills in job-related settings, thereby significantly facilitating competent new soldier selection. The aforementioned instrument can be considered one of the first situational judgment tests (SJTs). After World War II, several similar tests were designed to capture supervisory potential (e.g., Bruce, 1974; Cardall, 1942; File, 1945; Greenberg, 1963). In 1990, Motowidlo and colleagues framed the SJT as a new alternative measurement procedure for personnel selection (Motowidlo et al., 1990) and thereby reinvigorated interest in SJTs among scientists and practitioners. SJTs present test-takers with realistic job situations, followed by potential response options out of which candidates have to select the most appropriate response (Motowidlo et al., 1990). SJTs are considered measurement tools that aim to capture job-related competencies and skills (Lievens et al., 2008). **Figure 1** shows an example SJT item.

Similar to assessment centers and work samples, SJTs are simulation-based instruments. Simulations are based on the

You and someone from another department are jointly responsible for coordinating a project involving both departments. This other person is not carrying out his share of the responsibilities. What would you most likely/least likely do?

1. Discuss the situation with your manager and ask him to take it up with the other person's manager.
2. Remind him that you need his help and that the project won't be completed effectively without a full team effort from both of you.
3. Tell him that he is not doing his share of the work, that you will not do it all yourself, and that if he does not start doing more, you'll be forced to take the matter to his manager.
4. Try to find out why he is not doing his share and explain to him that this creates more work for you and makes it harder to finish the project.
5. Get someone else from his department to help with the project.

Figure 1 Example situational judgment test item. Motowidlo, S.J., Hooper, A.C., Jackson, H.L., 2006. A theoretical basis for situational judgment tests. In: Weekley, J., Ployhart, R. (Eds.), Situational Judgment Tests. Jossey-Bass, San Francisco, pp. 57–81.

behavioral consistency logic (Lievens and De Soete, 2012). That is, the assumption that candidates' performance during the selection procedure will be consistent with their future performance on the job. The difference between SJTs and other simulation-based measurement instruments lies in their level of fidelity. Fidelity can be defined as the extent to which the selection procedure mirrors the actual job situation (Callinan and Robertson, 2000). As assessment centers and work samples require actual behavior during the selection phase, such instruments can be considered high-fidelity simulations. High-fidelity simulations are more expensive to administer and are therefore generally used in small samples, during later selection stages. In contrast, SJTs are described as low-fidelity simulations (Motowidlo et al., 1990) as they do not require test-takers to display actual behavior but instead confront them with written descriptions of realistic job situations. As a result, SJTs can be administered to large applicant groups in preliminary selection stages. Since their reintroduction by Motowidlo and colleagues in 1990, SJTs have become attractive selection instruments for practitioners who are looking for cost-effective instruments for measuring a wide variety of predominantly interpersonally oriented constructs.

SJT Development

The development of SJTs typically consists of three stages (Motowidlo et al., 1990). In the first stage, the stimulus material is developed. It is advisable to start this phase with a job analysis, so that the knowledge, skills, abilities, and other characteristics (KSAOs) are identified, which are considered to be crucial for job performance. For each of these competencies, critical incidents of work situations are gathered from subject matter experts (i.e., incumbents, their supervisors, clients) or from archival sources. As a next step, test developers select the best nonredundant critical incidents from the total pool and rewrite them into test items of similar length and format.

Second, the response options are developed. To this end, all items are presented to a different group of subject matter experts or to inexperienced employees, which are asked to formulate possible responses to the given job situations. In this stage, test developers aim to collect a satisfactory amount of responses for every single item, and these responses should capture a wide range of effectiveness.

As a third and last step, the SJT's scoring key is developed. Test developers mostly opt for a rational or an empirical scoring key. When developing a rational scoring key, subject matter experts are asked to either identify the best and the worst response options or to rate all responses per item on their effectiveness. Unlike the rational scoring key, an empirical scoring key does not use expert judgments. Instead, the SJT is administered among a large pool of incumbents, whose responses are then linked to a criterion (e.g., job performance). SJT responses that are mostly chosen by high performing employees are labeled as 'correct' or 'highly effective,' whereas the opposite takes place for SJT responses that are not endorsed by high-performing employees or selected by low-performing individuals.

SJT Design Considerations

Although most SJTs are designed according to the predefined steps described above, test developers and their clients also face various design decisions, which may impact on the specific outlook of the SJT developed. These decisions are typically driven by the available resources and the objectives (hiring, promotion, training, recruitment, etc.) one wants to accomplish with the SJT.

A first set of decisions concerns the characteristics of the item. A first aspect of the item stem that varies between SJTs is the *item length*. Some SJTs provide test-takers with a simple and short situational description (e.g., 'A colleague in your team dodges her duties and you have to take over a lot of her tasks.'), whereas others present the participant with detailed descriptions of the job situation and its background. Similarly, items may vary in their level of *contextualization*. Some SJTs are built to measure KSAOs for specific jobs, whereas others are meant to measure generic competencies or skills across several jobs on the same level. As a result, SJTs in the former category will often be characterized by a higher degree of contextualization than the latter types. Highly contextualized SJT items provide specified information about the organizational setting and job context, which is illustrated by mentioning job-specific equipment or by using job terminology. A final item-related difference between SJTs is their level of *interactivity*. Whereas traditional SJTs present each test-taker with the same (sequence of) items, interactive or so-called 'branched' or 'nested' SJTs take into account the test-taker's response to former items to decide, which items will be presented subsequently (Olson-Buchanan et al., 1998). Accordingly, test-takers are confronted with the consequences of their response actions. For example, if a participant decides to fire an unproductive employee in one item, the next item may deal with an uproar in the team as a consequence of the dismissal. The main advantage of these branched SJTs is that they permit to mirror the dynamics of an actual interaction, while maintaining a certain degree of standardization (Lievens et al., 2008).

Design decisions should also be made regarding the SJT's *stimulus and response modality*. Modality refers to the way the information is presented to the candidate (for stimuli) or the manner in which the candidates are required to answer (for responses). Regarding stimulus modality, SJTs traditionally have a text-based format that presents test-takers with written descriptions of job situations. As calls have been made to develop more realistic measurement instruments (e.g., Lane and Stone, 2006), i.e., instruments that show a greater resemblance with the actual job for which they are selecting applicants, written SJT stimuli can be replaced by video-based or multimedia stimuli (Chan and Schmitt, 1997; Weekley and Jones, 1997). In such SJTs, test-takers are presented with short videos of job-related situations. At a critical point, the video freezes and the test-taker is subsequently required to select the most appropriate response to the presented situation.

Regarding response modality, SJTs traditionally have a text-based multiple choice format, which present test-takers with a predetermined set of written responses. However, recently also alternative response modalities have made their entrance in the SJT domain. For instance, Kanning et al. (2006) experimented with video-based instead of written response options.

More recently, Crook and colleagues introduced the single-response SJT (Crook et al., 2011; Motowidlo et al., 2009). Single-response SJTs confront test-takers with only one response option, which they have to rate on its effectiveness by means of a Likert scale. The main advantage of single-response SJTs is their less labor-intensive test design. In contrast to traditional multiple choice SJTs, single-response SJTs require only one group of subject matter experts for test design, which are asked to come up with critical incidents that struck them as extremely effective or ineffective. Based on this information, both item stems and responses can be derived, and the second development stage of traditional SJTs can be skipped.

A third decision concerns the SJT's *response instructions*. Both knowledge-based and behavioral-based response instructions are frequently used (McDaniel et al., 2007). Knowledge-based response instructions ask the candidate to display their knowledge of the responses' effectiveness by selecting the best/worst response option ('What is the best/worst answer?') or by rating each response option on its perceived effectiveness. As a result, SJTs with knowledge-based instructions are measures of maximal performance. In contrast, SJTs with behavioral-based response instructions ask candidates to report how they would respond in the presented situation ('What are you most likely to do?') and are therefore considered as typical performance measures.

Finally, a fourth set of decisions deals with the SJT's *scoring key*. As has been mentioned earlier, empirical and rational scoring keys are the most common choices for scoring keys. Therefore, hybrid forms have also been developed. For instance, an extant empirical scoring key is given to experts to make sure that 'it makes sense.' Alternatively, one might start with an expert-scoring key and later on validate it empirically.

An Evidence-Based Evaluation of SJTs

Since Motowidlo launched the SJT as an alternative measurement procedure for personnel selection in the early 1990s (Motowidlo et al., 1990), research on SJTs has made great strides forward. Today, over 60 studies have been devoted to the development and psychometric properties of SJTs. On the basis of the available research, we review below SJTs in terms of their reliability, construct-related validity, criterion-related validity, incremental validity, subgroup differences, and test-taker perceptions.

Are SJT Scores Reliable?

To assess whether or not SJTs scores are reliable, most prior research has focused on internal consistency reliability. For example, a meta-analysis of McDaniel et al. (2001), based on 39 different SJTs and over 10 000 participants, found internal consistency reliability coefficients ranging from 0.43 to 0.94. A more recent study of Catano et al. (2012) revealed a corrected weighted mean internal consistency of 0.46 based on 56 coefficients.

The variety in internal consistency reliability coefficients is in the first place a function of the instrument's length. SJT scores based on more items generally demonstrate higher internal consistency reliability. In addition, Ployhart and Ehrhart (2003) found that response instructions may serve as a second driver of internal consistency variability in SJTs. More specifically, SJT response instructions requiring the participant to rate each response on its effectiveness by means of a Likert-like scale resulted in the highest internal consistency reliability coefficients. Instructions that asked participants to choose two response options (e.g., 'What is your most/least likely response?' or 'What is the most/least effective response?') displayed somewhat lower internal consistency reliability coefficients, and instructions requiring participants to select one single response option (e.g., 'What is your most likely response?' or 'What is the most effective response?') resulted in the lowest internal consistency reliability coefficients.

Besides test length and response instructions, the often observed heterogeneous nature of many SJTs is probably one of the main reasons for their low internal consistency reliability (Lievens et al., 2008). As most SJTs are heterogeneous at the item level and aim to capture a plethora of constructs, internal consistency may therefore not be the most preferred means to evaluate SJT scores' reliability. Instead, researchers have proposed that alternate-form reliability or test–retest reliability may be more appropriate in the case of SJTs (Whetzel and McDaniel, 2009). Unfortunately, both of these reliabilities are rarely reported. One recent exception is the study of Catano et al. (2012), which reported test-retest reliabilities ranging from 0.66 to 0.82.

What Do SJTs Measure?

As SJTs have been used to capture a wide variety of constructs, answering this question is a challenge. Over the past years, SJTs have been developed to measure several competencies as diverse as entry-level managerial skills (Motowidlo et al., 1990), leadership skills (Oostrom et al., 2012), team work skills (Prewett et al., 2013), emotional intelligence (Libbrecht and Lievens, 2012; Libbrecht et al., in press; Sharma et al., 2013), interpersonal skills of medical students (Lievens and Sackett, 2012), aviation pilot judgment (Hunter, 2003), personal initiative (Bledow and Frese, 2009), and integrity (Becker, 2005; De Meijer et al., 2010).

In an attempt to develop a content-based typology, Christian et al. (2010) identified and clustered all construct domains assessed by SJTs. They found that about 70% of the extant SJTs aim to capture either leadership or interpersonal skills. To assess which factors determine SJT performance, several meta-analyses have demonstrated a relatively high correlation between SJT performance on the one hand and cognitive ability measures or personality traits on the other hand. In terms of SJTs scores' relation with cognitive ability scores, meta-analyses reveal correlation coefficients ranging from $r = 0.32$ (McDaniel et al., 2001) to $r = 0.46$ (McDaniel et al., 2007). Four moderating factors for the relationship between SJT performance and cognitive ability can be derived from the literature. First, SJTs that are developed on the basis of a thorough job analysis seem to display higher correlations with cognitive ability than SJTs that do not start from a job analysis (McDaniel et al., 2001). Second, the more detailed the SJT question, the lower the SJT's correlation with cognitive ability appears to be (McDaniel et al., 2001). Third, several studies have emphasized the importance of the stimulus

format for the constructs assessed. For instance, SJTs with a video-based stimulus format demonstrate a lower correlation with performance on cognitive instruments than paper-and-pencil SJTs (Chan and Schmitt, 1997; Lievens and Sackett, 2006). Finally, in their meta-analysis in 2007, McDaniel et al. (2007) identified the response instructions as the fourth important influencer of cognitive saturation. That is, SJTs with knowledge-based response instructions display higher correlations with cognitive ability than SJTs with behavioral tendency instructions.

SJT scores have also found to be correlated with personality. McDaniel et al. (2007) demonstrated that an SJT's relation with personality traits is a function of its response instructions. That is, SJTs with behavioral response instructions show significantly higher correlations with Agreeableness ($r = 0.37$), Conscientiousness ($r = 0.34$), and Emotional Stability ($r = 0.35$) as compared to SJTs with knowledge-based response instructions ($r = 0.19$, $r = 0.24$, and $r = 0.12$, respectively).

What Do SJTs Predict?

One of the most important evaluation criteria when deciding whether or not to use selection instruments refers to the extent to which they are related to job-related performance domains. Meta-analytic research has confirmed the expectation that SJTs are valuable predictors of job performance. A first meta-analysis on the criterion-related validity of SJT scores revealed a validity coefficient of $r = 0.34$ for predicting job performance (McDaniel et al., 2001). As one of the most important moderators of criterion-related validity, McDaniel and colleagues demonstrated the presence or absence of a job analysis to be an influential factor. SJTs that were based on a thorough job analysis displayed higher validity than SJTs that did not use a job analysis as their starting point. Several years later, a second meta-analysis was undertaken, which included more data than the former and which revealed an estimated population criterion-related validity coefficient of $r = 0.26$ (McDaniel et al., 2007). The most recent meta-analysis on criterion-related validity of SJTs thus far was published in 2010. On the basis of 84 studies, Christian et al. (2010) found validity coefficients of $r = 0.38$ for SJTs measuring teamwork, $r = 0.28$ for SJTs on leadership, and $r = 0.25$ for SJTs capturing interpersonal skills. Additionally, two extra moderators of SJT criterion-related validity were identified. First, the importance of careful predictor-criterion matching was emphasized as SJTs measuring specific competencies (e.g., interpersonal skills) demonstrated the highest validity for predicting matching criteria domains (e.g., interpersonal job performance, see also Lievens et al., 2005). Second, it was found that an SJT's stimulus modality may influence its criterion-related validity. More specifically, video-based SJTs displayed higher criterion-related validity coefficients than text-based SJTs for predicting interpersonal skills (see also Lievens and Sackett, 2006).

Apart from showing sufficient criterion-related validity in employment settings, SJT scores have also found to be useful for predicting academic success. For example, Lievens and colleagues repeatedly demonstrated that SJTs are good predictors of academic performance among student physicians (Lievens, 2013; Lievens et al., 2005; Lievens and Sackett, 2006, 2012). In a similar vein, Oswald et al. (2004) developed an SJT for predicting student performance. Their SJT aimed to capture 12 dimensions of college student performance and was successful in predicting academic success.

Finally, SJT scores have demonstrated consistent incremental validity over and above scores on more established selection instruments (Clevenger et al., 2001). This implies that SJTs succeed in predicting unique variance in criterion performance, which cannot be accounted for by other predictors. Various studies have demonstrated incremental validity of SJTs for predicting job or academic performance over cognitive ability, job knowledge, job experience, and personality (Chan and Schmitt, 2002; Clevenger et al., 2001; Lievens and Patterson, 2011; McDaniel et al., 2001, 2007; O'Connell et al., 2007; Oswald et al., 2004; Weekley and Jones, 1997, 1999). In their meta-analysis, McDaniel et al. (2007) estimated the incremental validity of SJTs over cognitive ability between 3 and 5%, with somewhat higher incremental validity coefficients when behavioral instead of knowledge-based response instructions were used. Additionally, it was found that SJTs provide incremental validity over personality, varying from 6 to 7%, with the highest incremental validity for SJTs with knowledge-based response instructions. Over a combination of cognitive ability and personality, SJTs provided incremental validity of 1–2%. Besides response instructions, also the criterion type has been proven to be an influential factor of incremental validity variability (O'Connell et al., 2007). For instance, O'Connell and colleagues found incremental validity for SJTs over cognitive ability but not over personality for predicting contextual performance, whereas this was not the case for predicting task performance. More research is needed to confirm this finding on a more general level, though.

Recently, conceptual progress has been made to explain why SJTs are valid predictors. According to Motowidlo and Beier (2010), SJTs measure general as well as specific knowledge of the costs and the consequences of job-related actions. General knowledge refers to implicit knowledge about the relationships between expressions of personality traits and effective job performance (i.e., implicit trait policies). That is, such general knowledge refers to people's judgments about the costs and benefits of engaging in courses of action as response to SJT situations. Specific knowledge is different from general knowledge because it is limited to specific job situations, which may include exceptions to successful trait policies (e.g., specific job situations where assertive reactions are more valued than agreeable reactions). The combination of both knowledge types captured by SJTs is assumed to be predictive of effective performance.

What about SJTs and Diversity?

An additional reason for the popularity of SJTs in the field of personnel selection is that they are introduced as 'alternative' predictors, which might display smaller subgroup differences than cognitive ability tests. So far, the research evidence is a bit more mixed. Ethnic subgroup differences on SJTs have varied from approximately one standard deviation (Chan and Schmitt, 1997) to almost zero (Olson-Buchanan et al., 1998), with Caucasians obtaining higher scores than black ($d = 0.38$), Hispanic ($d = 0.24$), Asian ($d = 0.29$), and

European minority ($d = 0.38$) test-takers (De Meijer, 2008; Whetzel et al., 2008).

Some factors may explain the great variety in subgroup differences assonated with SJT scores. First, meta-analytic research identified cognitive loading as one of the most important drivers of ethnic subgroup differences in SJT performance. Cognitive loading refers to the extent that SJT performance correlates with performance on a cognitive ability test. Similar to assessment centers and work samples (Bobko et al., 2005; Dean et al., 2008; Roth et al., 2008), SJTs with a higher cognitive loading display substantially larger ethnic subgroup differences (Roth et al., 2013; Whetzel et al., 2008). Second, the personality loading, i.e., the correlation between the SJT and each of the Big Five personality factors, has been identified as a smaller driver of ethnic subgroup differences in SJTs, so that black–white and Asian–white differences in SJT performance are smaller when the SJT displays a higher correlation with emotional stability and Hispanic–white differences are smaller when the SJT displays a higher correlation with conscientiousness and agreeableness (Whetzel et al., 2008). Third, SJT response instructions have been shown to influence ethnic performance differences. Knowledge-based response instructions ('What is the best response?') generally lead to larger ethnic subgroup differences than behavioral tendency response instructions ('How would you respond?'), which is most likely due to the greater cognitive loading of SJTs with knowledge-based response instructions (Whetzel et al., 2008). A fourth moderator concerns the SJT response process. SJTs that require candidates to rate each response option's effectiveness by means of a Likert scale are more susceptible to ethnic subgroup differences because SJT performance is influenced by the white–black difference in extreme scoring preferences. By controlling for elevation and scatter in responses, black–white performance differences on this SJT type are substantially reduced. In addition, this correction is particularly promising as it simultaneously improves validity (McDaniel et al., 2011).

In terms of gender differences in SJT performance, a meta-analysis demonstrated that female test-takers on average perform slightly higher than male test-takers ($d = -0.11$; Whetzel et al., 2008). Larger female advantages occur when the SJT is more correlated with agreeableness and conscientiousness (Weekley et al., 2004; Whetzel et al., 2008).

Do Candidates Like SJTs?

A last aspect for evaluating SJTs relates the test perceptions. In general, simulation instruments, such as assessment centers, work samples, and SJTs, are more favorably received by applicants than cognitive ability tests, personality inventories, biodata, and integrity tests (Hausknecht et al., 2004; Oostrom et al., 2010). Some researchers have identified specific SJT factors, which may influence test perceptions or attitudes. One of the most important drivers of test perceptions in SJTs thus far, seems to be the stimulus modality. Richman-Hirsch et al. (2000) examined the effect of stimulus modality on test perceptions and attitudes for three content-wise identical conflict management SJTs. The first SJT had a paper-and-pencil format. The second SJT was identical to the first but used a computer screen and an automatic page turner to display the information. The third SJT presented test-takers with exactly the same scenarios but in video format. Applicants watched videos of job-related conflict situations and were asked to select the best response out of a set of four written options. Results demonstrated that test-takers reported significantly more favorable face validity perceptions and test attitudes for the video SJT as compared to the other two formats. Furthermore, there was no difference in reported perceptions and attitudes between the paper-and-pencil SJT and the computerized version, which suggests that computerizing test content is not sufficient to influence test perceptions. Along the same lines, Chan and Schmitt (1997) compared a written SJT with a content-wise identical video variant. They found significantly higher face validity perceptions for the latter SJT. Finally, Kanning et al. (2006) examined which SJT factors improve test perceptions. They discovered that changing the stimulus or response modality from written to video format alone was not enough to increase test perceptions, but that interactive SJTs with video stimuli as well as video response options received the most favorable test perceptions.

Epilogue

In the last two decades, SJTs have become a popular selection instrument that is widely used by practitioners and intensively studied by researchers. Their popularity in the field of personnel selection can largely be accredited to the potential of SJTs to capture a variety of constructs, in diverse settings, and for different purposes. Additionally, research has repeatedly proven that SJTs are able to predict several job-related and/or academic criteria while at the same time offering prospects permitting to select for diversity.

Moreover, the future of SJTs for research and practice is looking bright. At the risk of being self-promoting, below we give a brief overview of some of our own research priorities in the next years. One avenue that we see as increasingly important is the use of SJTs in cross-cultural settings. To this end, research is needed to examine the intercultural transportability and robustness of SJTs (see Lievens, 2006; for an overview). Second, calls have been made to increase our conceptual understanding of the different components of SJTs and their effects on key selection outcomes. Here we advocate the use of a building block approach (e.g., Arthur and Villado, 2008; Lievens et al., in press). That is, instead of treating SJTs as holistic entities, the SJT method can be conceptualized as a combination of various predictor method factors (i.e., response instructions, stimulus format, response format, etc.). By keeping other factors constant, researchers are able to identify the impact of specific SJT factors on the criterion of interest (e.g., construct-related validity, criterion-related validity, subgroup differences, Chan and Schmitt, 1997; Lievens et al., in press; Lievens and Sackett, 2006). Finally, we believe that the SJT domain would benefit from incorporating novel presentation and response formats. Successful examples are 3D animated and avatar-based SJTs (Fetzer, 2012). Another example is the development of video-based SJTs with an open-ended response modality, namely

either a written (responding in a text box) or behavioral (responding through a Webcam) response format (Lievens et al., in press). Clearly, there exist a plethora of opportunities to create new SJT formats and hybrid SJTs in the future. Both practitioners and researchers should join forces to implement and examine them in the future.

Skills Training: Public Policy Aspects

Moira Nelson, Lund University, Lund, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article describes factors influencing investments in skills training as well as related outcomes in terms of participation rates and benefits on an individual and societal level. Market mechanisms largely drive human capital investments. According to this logic, workers and employers conduct a cost–benefit analysis, weighing expected payoffs against expected costs and investing accordingly. At the same time, market failures and collective action problems may occur in the provision of training. Various policies and institutions have been shown to resolve such problems and boost training. Whereas participation rates vary widely by firm characteristics, high rates of participation help countries specialize in high-quality production and achieve high job satisfaction.

Introduction

Various factors shape skills investments and their related benefits on an individual and societal level. Following largely from market mechanisms of supply and demand, skill investments are made which increase worker productivity and thereby wages for employees and profits for employers. This logic goes some way in explaining individual and overtime trends. At the same time, there are many reasons to suspect training to be undersupplied, due to informational deficiencies, capital market imperfections, and the risk that workers do not stay with the training firm long enough to repay the firm in the form of productivity increases. With respect to the issue of worker mobility, Becker theorized that employers should only provide training in specific skills. Available data, however, shows employers do invest in general training and various theories offer explanations for why this is the case, oftentimes with reference to the concepts of market failure and collective action problems. Moreover, overeducation also occurs, resulting in the existence of a significant mismatch between the required and actual skills of the workforce.

Participation in skills training varies widely across types of individuals and countries. Younger workers enter into training more often because the horizon of expected payoffs is longer and foregone earnings lower. More productive workers are trained more often because the wage premia is higher. Training rates vary depending on the structure of initial vocational training, continuing training policies, and economic context. If countries are able to realize high rates of participation in training, various benefits are identified including a comparative advantage in high-quality production and high job satisfaction.

Markets for Education and Training

Economic theory reaching back at least 200 years to Adam Smith tells us that competitive markets provide incentives for employers and workers to invest in training. Training occurs because the future (discounted) payoffs outweigh the costs (Becker, 1980). Analyses often consider the direct costs of training as well as the opportunity costs. The following model expresses well the cost–benefit analysis of training,

$$B_{\mathrm{i}}\left(1-(1/r)^{N}\right)\Big/r > K + Y_0 \qquad [1]$$

whereby B_{i} indicates the earnings gained due to schooling, which are presumed to be constant throughout one's working life, N is to the years left in one's career, r is the discount rate on future gains, K is the direct costs of schooling, and Y_0 is foregone earnings during the schooling period. As long as discounted earnings gained from schooling is higher than the sum of the costs of training and foregone earnings, training takes place. The model allows us to derive a few stylized facts about when training will occur which are often upheld in empirical studies. Younger people are expected to engage in more training because they have a longer horizon of higher returns and lower foregone earnings due to seniority pay scales (as N increases, benefits to train increase). Participation among young people indeed tends to be higher, although more disaggregated analysis suggests that effects vary by individual characteristics and type of training.

Skill training activity is also expected to increase when the costs of training decrease (as K decreases, benefits to training increase). Public subsidization of training is generally supported, although theoretically justifying such action requires proof that market mechanisms fail to meet demand which is empirically quite challenging. A randomized experiment using adult training vouchers showed that the provision of such vouchers increased training activity (Messer and Wolter, 2009). At the same time, deadweight costs were also quite substantial at around 50% which underscores the risk that subsidizing training does not actually increase participation on the aggregate.

Finally, eqn [1] predicts that workers who expect a high wage premium from training are more likely to participate (when B_{i} is high relative to Y_0) (Heckman et al., 1999). The evidence strongly supports the expectation that more productive and well-educated workers are more like to be training. There are many different reasons given for this finding. In addition to expecting higher returns, such workers tend to receive more intrinsically motivated. Employers thus hold a distinct bias toward training these workers since the payoff is relatively higher.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.75010-0

Wage premiums are also influenced by economic changes that alter demand for different types of skills. Technological changes and globalization, for instance, generally lead to increases in the level of skills demanded in the labor market. As demand for more highly trained workers increases without a parallel increase in supply, the wage premium associated with higher training increases. Conversely, the entrance of large cohorts of well-educated workers into the labor market has the effect of pushing down the wage premium. This effect is visible in the United States in the 1970s and can also be seen in Korea and Japan (Kim and Topel, 1995).

Causes of Underinvestment in Skills Training

Various theoretical perspectives on skills training challenge the expectation of traditional economic theory that markets always lead to the optimal level of training activity. A central insight here is that encouraging skills training relies on policies and regulations that make workers and employer aware and secure of the future benefits of investing in training.

Concepts of market failures and collective action problems are useful in explaining deficiencies in the market provision of training. Market failures arise due to lack of information about the potential gains from or lack of financing for training and collective action problems occur because the gains to training cannot be fully internalized by the investor. Particularly as skill needs change quickly in response to technological advancements, difficulties may arise in estimating the appropriate scale and content of new training programs. Furthermore, the payoffs from training may be underestimated by either workers or employers. There may be capital market problems whereby workers are unable to get financing for training which would deliver returns in the future (Dougherty and Tan, 1999). The International Adult Literacy survey reveals that time constraints are by far the main reason for nonparticipation.

Beyond market failures, collective action problems arise in the provision of skills training essentially because workers are mobile and can leave the firm which provided them with training. Employers therefore face a risk in training workers, because training stands to improve workers' productivity in competing firms. Often used to analyze incomplete contracting with relation to physical goods, the concept of asset specificity has been used to understand collective action problems in relation to skill investments. Specific assets are those that cannot be readily applied to a different purpose or whose return depends heavily on the cooperation of others. The degree of skill specificity has been widely used to explain employer incentives to train.

In a seminal contribution, Gary Becker (1993) sees the specificity of skills as largely inherent to the skill itself and expresses the willingness of employers to invest in workers' skills as a function of their specificity. The inclination of employers to fund training increases proportionally to the specificity of the skills being delivered. In Becker's account, market failures do not occur and the appropriate level of training always takes place, so long as workers are able to finance training (Acemoglu and Pischke, 1999).

Many have questioned the main claim of Becker's theory that firms only pay for firm-specific skills training, largely due to the observation that large-scale investments in general skills training indeed take place. Some go as far to claim that even investments in technically specific skills are in some way general if they signal that the worker is competent and motivated, in which case one may contend that all types of training are *de facto* general to some degree. Other modifications to Becker's argument have been made. The costs associated with employee turnover, labeled 'transaction costs,' lead both the employer and the employee to seek alternatives to termination via compromised solutions within the firm. 'Monopsonistic' labor markets allow employers to restrict workers' mobility regardless of their skill sets. General training can also be seen as a side payment, provided to encourage the worker to partake in training in specific skills (Kessler and Lülfesmann, 2006). A more compressed wage structure also leads to higher training by increasing the returns to training for the firm. Perhaps through their influence on the wage structure, strong unions are also related to a higher incidence of training. One can generalize that firms provide general training when carrots or sticks are used to limit worker mobility. Economists discuss these factors which limit mobility as producing labor market imperfections (Acemoglu and Pischke, 1999, 1998).

The Varieties of Capitalism approach sees various social policies and regulatory institutions as supporting investments in specific skills (Hall and Soskice, 2001). With respect to industry-specific skills, unemployment insurance provides workers with incentives to invest while standard-setting procedures ensure the uniformity of training and monitoring mechanisms protect against poaching. This approach also recognizes that *workers* need incentives to invest in firm-specific skills, a point not raised in Becker's more employer-centric account and sees employment protection as providing such an incentive.

To summarize, market failures and collective action problems arguably lead to suboptimal levels of training activity. Becker presumed that this would not occur so long as workers invested adequately in general skills training. Yet workers face considerable informational, time, and financial constraints in undertaking such training. Moreover, most training is not solely firm specific, not least because high levels of firm-specific skills signal the general capacity to learn and be productive in the workplace. Various contributions show that market imperfections, created informally in the workplace or institutionalized through such policies as unemployment insurance, provide incentives for workers and employers to invest in training despite associated risks.

Data on Participation Rates and Trends within and between Countries

The term 'coordinated market economies' refers to countries predominantly in continental and northern Europe which exhibit strong welfare states along with high investment in specific types of skills. In contrast, 'liberal market economies,' including the Anglo-Saxon countries, exhibit lean welfare states and excel in the provision of general training. These differences in training activity have important implications for working conditions and comparative advantage in product markets.

The coordinated market economies exhibit higher levels of vocational training, and investment in this type of training is

sustained by institutions that bring employers, workers, and policymakers together and provide them with incentives to compromise over the future orientation of training policy. Finegold and Soskice (1988) importantly recognized the high-skill equilibrium in Germany and the low one in the United Kingdom and traced these differences in skill investments back to the complex net of socioeconomic institutions in the former and the lack thereof in the latter. Crouch et al. (2001) identify three types of socioeconomic institutions related to training: state led, corporatist networks, and markets. In state-led systems, most vocational training takes place in schools (e.g., Sweden, France). In corporatist settings training is done in firms (e.g., Austria, Germany), and in market-based systems there is little vocational training at all. Technological change and tertiarization challenge vocational training systems in diverse ways (Busemeyer and Trampusch, 2011).

Estimating participation rates in training for all categories of workers is complicated because of the variety of training types provided and the lack of systematic data collection. Training may be long term and involve a formal training contract. However, most training is informal which frustrates getting a sense of trends (Lynch, 1994). Skills are often gained through a process of trial and error, by imitating what other workers do and receiving informal supervision from more senior employees.

The US Bureau of the Census' Current Population Surveys (CPS) provides data on workplace training in the United States and reveals that a large proportion of training is indeed carried out informally. In Europe, the Continuing Vocational Training Survey (CVTS) conducted by the European Union provides detailed data about participation in training. The type of training is broken down into five categories: in-work vocational training, self-learning, quality circles, job rotation, and training at conferences/lectures/workshops/seminars. The correlation between these different types ranges between 0.71 and 0.91, with an average of 0.82, which suggest that trends in informal forms of training are a good proxy for more formal training activities.

The CVTS also reveals that training occurs most often in two industries, 'electricity, gas, and water supply' as well as 'financial intermediation,' and least often in 'hotels and restaurants.' Training activity also varies significantly by firm size with larger firms almost always providing training to at least some employees and medium-sized (50–249) and small (10–49) firms offering proportionally less training, respectively. In some countries the gap between different sized firms is small (e.g., Norway, UK) while in others it is quite large (e.g., Greece, Bulgaria).

Participation tends to be slightly procyclical, although there is evidence that training might actually increase during economic downturns. Reconciling these findings, Brunello (2009) explains that employers train existing workers more during downturns and slow the recruitment of new workers.

Public and Semi-Public Policies on Training

Public policies promote training by delivering financial support as well as regulating both the content and completion of training through curricula development and certification, respectively. In most cases, training is financed privately either by the employer or by the worker. However, there are also ways in which the costs of training are socialized. The state often provides funds for training through general taxation, although the amount provided varies tremendously across countries. The Nordic countries are widely known as high spenders. Besides providing funds, the state may also make training financially viable by offering tax rebates to training firms.

Tax levies on firms are another way in which to raise funds for training. Levies may be legally enforced by the state, as in France, or coordinated by employer organizations, as in the Netherlands. Levies typically call on firms to pay a particular percentage of wages into a common pool. Other times risk pooling occurs in more informal ways. For instance, in Germany larger firms historically 'overtrain' to the benefit of smaller firms and therefore subsidize the training costs of smaller firms to some extent.

The state and employers are also heavily involved in regulating curricula and certification. Curricula are often reformed in response to shifts in supply and demand, as periods of tight labor markets provide incentives to broaden occupational profiles. Technological change and more fluid labor markets can also be seen to stimulate consolidation of occupational profiles, since identifying the overlap between different skill sets becomes more important. Certification is key in communicating the skills that training has provided. Flexible certification procedures have become more renowned in the past few decades, such as accreditation of prior learning, modularization, and national qualification frameworks.

Estimates of the Amount Invested in Training

A common way to estimate training costs is the ingredients method according to which all the relevant components, or ingredients, of training are identified, the costs of each estimated, and all of them summed (Levin, 1983; Mincer, 1994). Ingredients usually include workers' and trainers' time, instruction materials and facilities. In reality, many difficulties exist in estimating the costs of various ingredients (Tsang, 1999). Calculating costs in this ways relies on detailed information about how workers spend their time, which is typically collected in the form of a diary. Clearly a costly method, it is not used often, particularly for large samples.

Another way to estimate training costs is to deduce the amount of training conducted from the rate of earnings growth over the career (Mincer, 1962). Evidence indeed shows that training firms experience larger wage growth than nontraining firms. At the same time, earnings growth may result from other factors besides training, which may lead this approach to overestimate investments in training in the case of general skills. For instance, workers often change jobs to receive better pay and earnings growth in this case would be the effect of bargaining power rather than training. In the case of specific skills, however, this approach would underestimate the amount of training provided since earnings would not rise in line with productivity increases. Studies that show that the effect of training is higher for productivity than on wages support this view (Ballot et al., 2006; Dearden et al., 2006).

The net costs of training are widely shown to be negative during the apprenticeship period. German apprenticeship training was estimated at 12 300 DM in 1985 (Franz and Soskice, 1995) and, with different data based on a 1991 survey, found to exceed for certain 7500 DM (Bardeleben et al., 1995). A recent study of Swiss firms reveals that net training costs did not have an impact on the number of trainees, despite the relatively high risk of poaching in the Swiss context (Muehlemann et al., 2007). This finding cautioned against the subsidization of apprenticeship training.

The CVTS also provides rich data on spending on continuing training. In 2005, spending as a percentage of labor costs was highest in Denmark (2.7%) and France (2.3%) and lowest in Latvia (0.8%) and Greece (0.6%). Additional data break down costs by hour, individual, industry, size class, and type of cost.

Given that credit constraints are recognized as a major reason why training does not occur, many countries have negotiated cofinancing arrangements to boost participation. The costs of training are often made tax deductible. Learning accounts and training vouchers are also widely used, whereby the state or the employer usually matches contributions made by participants. Additional incentives are usually made for low-skilled workers.

The Benefits of Training for the Individual and Society

The relationship between participation in training and higher wages is strongly supported by the literature. Research suggests that the gross returns to wages from a year's worth of vocational training is approximately 10% per year or more (Mincer, 1994).

Often unclear, however, is whether training drives wage increases or if those who receive training were simply more productive in the first place. Disentangling these effects is tricky because of selection bias. Workers with a higher relative level of education are far more likely to enter a training program than others (Brunello and Comi, 2004). As a result, training often has the effect of increasing labor market segmentation.

In terms of apprenticeship training, there is a tension between firms' use of apprentices as an immediate source of productivity, by substituting normal workers with apprentices, and as an investment whereby employers devote energy to improving the skill base of apprentices with an eye on creating the future workforce. In a recent study of Germany, firms are shown to follow both strategies (Mohrenweiser and Backes-Gellner, 2010). Firms that use a substitution method tend to use apprentices as cheap labor, as evidenced with data from Norway (Askilden and Nilsen, 2005) and the Netherlands (Smits, 2006). Smits (2006) finds that firms which follow an investment strategy provide higher quality training.

Rather than comparing quality of apprenticeship training, other studies distinguish those countries which invest highly in vocational skills, the coordinated market economies discussed in Section Causes of Underinvestment in Skills Training, to countries which tend to provide general skills training, the liberal market economies. Within this group, Germany is often singled out and the high level of investment in apprentices. Such training also leads to a comparative advantage in high-quality diversified production (Streeck, 1992) which depends on highly training workers (Soskice, 1999). Others point out that the vocational skills are oftentimes provided by schools rather than firms, an empirical tendency often over looked in the literature (Busemeyer, 2009). Given the challenges in encouraging firms to provide general skills, the school component of vocational programs is a propitious way to expand this type of training, particularly as economic change calls for a stronger base in precisely these types of skills. In Denmark, while most training occurs in firms, the state has often used vocational schools to expand the general skills component of training and thereby facilitate adjustment to economic change (Nelson, 2011).

Beyond the need for stronger general skills, various economic changes necessitate lifelong learning. Technological change and other competitive pressures create the need to invest frequently in updating one's skill profile to remain competitive on the labor market. Expanding opportunities to acquire skills and clear certification mechanisms improve the ability of countries to adjust to this changed context (Nelson, 2010).

A particular way to promote learning involves restructuring workplace relations to facilitate discretionary learning. Discretionary learning refers to a form of work organization whereby workers receive considerable autonomy yet also responsibility to independently resolve issues that arise, often by teaching themselves new tasks. The Nordic countries exhibit the highest levels of discretionary learning which partially explains their smooth adaptation to the knowledge economy and low numbers of Taylorist jobs in these countries (Lundvall and Lorenz, 2011a,b).

Skill Availability

The onset of the knowledge economy significantly alters the skills demanded in the labor market. Many of the new jobs being created in high-wage services involve advanced cognitive skills. Interpersonal and communication skills are also in high demand. Technological change and intense global competitive pressures also make updating one's skill set as job profiles and modes of production continue to change. Both strong initial education and access to continuing training are necessary for remaining competitive in the labor market. If education reforms do not keep pace with rising skill needs, the risk of a risk shortage increases.

Yet the phenomenon of overeducation also exists, whereby the increase in educational attainment outstrips the rising skill needs of employers. Overeducation derives largely from competition over jobs whereby potential applicants attempt to gain a competitive advantage by gaining an additional qualification.

Skills mismatch refers to the gap between the skills required by a worker to complete their job and the skills that they have. It is often measured as the combined proportion of the workforce that is undereducated and that which is overeducated. The ILO (2013) estimates that there is a mismatch of between 30 and 50% of the workforce in European countries. Although the sample differs, a report by the OECD suggests the proportion to be closer to 50 (Quintini, 2011).

Concluding Remarks

The issue of skills training has received much attention in recent years. Classical economic theory contends that the optimal level of training is provided through market mechanisms. That is, training always occurs if and only if there is reason to expect a net gain in terms of productivity. For supporters of this perspective, subsidizing training leads to high deadweight losses and is an inappropriate use of government funds.

There are nevertheless reasons to expect market failures and collective action problems to lead to a suboptimal level of training activity. Workers and employers likely face enormous hurdles in recognizing valuable training opportunities and allocating the time and resources necessary to ensure successful completion of these programs. Moreover, most training involves the provision of more general skills which generate insecurities among employers about workers being poached by competing firms. To relieve this fear, the literature illuminates the positive role that various informal and formal policies and institutions can play. Workers and employers may find mutually beneficial solutions among themselves or employers may manipulate their monopsony power to retain workers. Various social policies, labor market regulations, and other institutions are able to reduce the risk facing workers and employers investing in either general or specific skills.

Whereas caution must be exercised in deciding how and when to subsidize and regulate training activity, there appear to be considerable payoffs to both individuals and society more generally from realizing high rates of participation in training. Training is strongly related to higher wages and, if numbers are sufficiently high, countries are able to realize a comparative advantage in high-quality production. At the same time, the high rates of skill mismatch in the workforce today suggest that there is room to improve the alignment between training programs and market needs. Targeted training policies are particularly salient today since the economic crisis has triggered a new rise in skills mismatch (ILO, 2013).

Abstract

American psychologist, a leading figure of behaviorism, Skinner contributed original laboratory techniques for the study of operant behavior; a formulation of the nature of a science of behavior (radical behaviorism), a selectionist view of the causation of animal and human conduct inspired by the biological evolution model; and proposals for applications derived from his experimental and theoretical work to education, psychological treatment, and social organization. He broadened the scope of the behavioristic approach by including verbal behavior and consciousness in his analysis.

After J.B. Watson, the founder of the behaviorist movement, Skinner has been the most influential, and also the most controversial, figure of behaviorism. His contributions to behavioral sciences are manifold: he designed original laboratory techniques for the study of animal and human behavior, which he put to work to produce new empirical data in the field of learning, and to develop a theory of operant behavior that led him eventually to a general psychological theory; he further elaborated the behaviorist approach, both refining and extending it, in a version of behavioral science which he labeled 'radical behaviorism'; he formulated seminal proposals for applied fields such as education and psychological therapy and pioneered in machine-assisted learning; finally, building upon his conception of the causation of behavior, he ventured into social philosophy, questioning the traditional view of human nature and of the relation of humans to their physical and social environment. This part of his work has been the main source of sometimes violent controversy.

Biographical Landmarks

Skinner was born on 20 March 1904 in Susquehanna (Pennsylvania, USA) in a middle-class family and experienced the usual childhood and adolescence of provincial American life. He attended Hamilton College, which was not a particularly stimulant institution to him. He was first attracted by a literary career, which he soon gave up, after traveling to Europe. He turned to psychology and was admitted at Harvard in 1928. He obtained his PhD in 1931, with a theoretical thesis on the concept of reflex – a first landmark in his reflections on the causation of behavior, an issue he was to pursue throughout his scientific career. He stayed at Harvard five more years, beneficiary of an enviable fellowship, affiliated to the physiology laboratory headed by Crozier. In 1936, he was appointed professor at the University of Minnesota where he developed his conditioning chamber for the study of operant behavior in animals – which was to be known as the Skinner box – and wrote his first book *The Behavior of Organisms* (1938). In 1945, he moved to Indiana University, as chairman of the Department of Psychology. In 1948, he was offered the prestigious Edgar Pierce Professorship in Psychology at Harvard University, where he was to stay until his death on 18 August 1990.

Skinner received during his lifetime the highest national awards an American psychologist could receive, and he was praised as one of the most prominent psychologists of the century, in spite of harsh attacks against some of his ideas, from the most opposite sides of scientific and lay-people circles.

Although most of Skinner's laboratory research was carried out with animal subjects, mainly rats and pigeons, using the so-called operant procedure that will be described hereafter, essentially he was interested, not in animal behavior proper, but in behavior at large, and more specifically in human behavior. After the tradition of other experimental psychologists before him, such as Pavlov and Thorndike, and of most of his colleagues in the behaviorist school of thought, such as Hull, Tolman, or Guthrie, he resorted to animals as more accessible subjects than humans for basic studies on behavior, just as physiologists used to do quite successfully. The relevance of extrapolating from animals to humans is of course an important issue in psychology, still debated today. However, Skinner's main concern was obviously with humans, as evidenced by his literary writings in the field of social philosophy – namely the utopian novel *Walden Two* (1948) and the essay *Beyond Freedom and Dignity* (1971) – as well as by his theoretical endeavors to account for human behavior (*Science and Human Behavior* 1953) and for verbal behavior (*Verbal Behavior* 1957). A detailed autobiography in three volumes has been published by Skinner during his lifetime (1976, 1979, 1983).

Operant Conditioning and the Skinner Box

The operant conditioning chamber, often called the Skinner box, is a laboratory device derived from Thorndike's puzzle box and from the mazes familiar to students of learning in rats by the time Skinner started his career. In its most common form, it consists of a closed space in which the animal moves freely; it is equipped with some object that the subject can manipulate easily, be it a lever for rats, or a small illuminated disk upon which pigeons can peck, and with a food dispenser for delivering calibrated quantities of food. By exploring spontaneously this particular environment, the subject will eventually discover the basic relation between a defined response, pressing the lever or pecking the key, and the presentation of a reinforcing stimulus, a small food reward. The process involved is basically trial-and-error learning, as captured since Thorndike in the Law of Effect.

Learning this association can be facilitated by shaping progressively the desired behavior; in that case, the

experimenter observes systematically the subject's behavior, and reinforces selectively those actions that come closer and closer to the response required. The importance of that procedure will be commented further in relation with the concept of variation and with the issue of teaching. The basic relation here is between an operant response (i.e., a response instrumental to produce some subsequent event) and its consequence (i.e., the reinforcement), rather than between a stimulus and a response elicited by it, as in Pavlovian or respondent conditioning. This simple situation may be made more complex either by introducing so-called discriminative stimuli, the function of which is not to trigger the response at the manner of a reflex, but to set additional conditions under which the response will be reinforced, or by changing the basic one response-one reinforcement link to some more complicated contingencies, for instance requiring a given number of responses to one reinforcement, or the passing of some defined delay. A wide variety of schedules of reinforcement have been so studied, be it for their own sake as sources of information on the lawfulness of behavior (for instance, modern research has applied optimization models borrowed from economics to the study of operant behavior), or as efficient tools for other purposes (such as the analysis of sensory functions in animal psychophysics, of the effects of drugs acting upon the central nervous system in experimental psychopharmacology, or of cognitive capacities).

The operant technique presented two important features by the time Skinner developed it from the 1930s to the 1950s. It emphasized the study of individual subjects through a long period of time rather than groups of subjects for a few sessions, as used to be the case in maze studies and the like. This interest in individual behavior would favor later applications to human subjects in educational and clinical settings. Second, the operations involved soon were automatized by resorting to electromechanical circuits, to be replaced later by online computer control. This led to a level of efficiency and precision unprecedented in psychological research.

The Evolutionary Analogy

Skinner captured the essence of operant behavior in the formula 'control of behavior by its consequences,' and very early he pointed to the analogy between the selection of the response by the subsequent event and the mechanism at work in biological evolution. An increasingly large part of his theoretical contributions were eventually devoted to elaborating the evolutionary analogy (Skinner, 1987). The generalization of the selectionist model to behavior acquisition at the individual level, initially little more than a metaphoric figure, has later gained credentials with the theses of neurobiologists, such as Changeux's *Generalised Darwinism* (1983) or Edelman's *Neural Darwinism* (1987), who both have substantiated in ontogeny selective processes previously reserved to phylogeny. One of the main tenets of Skinner's theory converges with contemporary views in neurosciences.

Skinner extended the selectionist explanation to cultural practices and achievements, converging with some schools of thought in cultural anthropology, such as Marvin Harris, and in the history of science, such as Karl Popper's selectionist account of scientific hypotheses.

In Darwinian evolution, a crucial condition for selection to take place is the presence of variations. At the behavioral level, in the simplified situation of the experimental chamber, these can be observed in the exploring activities of the animal subject, eventually resulting in the discovery of the appropriate response. Once acquired, it might appear as the product of rigid training, eliminating variability, and consequently the possibility of new behavior. In fact, variability itself can be taken as the property to be selected, as shown by experiments in humans and animals. As Skinner argued, creative behavior would fit in the general selectionist scheme.

Biological evolution is responsible for the genetic endowment of organisms. Selection accounts for their specific characters, including important behavioral aspects. Ethology, sometimes called biology of behavior, has been mainly devoted to the study of these aspects, insisting on the necessity of observing animals' behavior in the natural environment, rather than put them in the artificial situation of the laboratory. Ethologists have also been very critical toward the focus on environmental factors dominant in the behaviorist approach. Behaviorists, working on learning processes, were blamed for ignoring the genetic contribution in specific behavior, including in the human species, whose members at birth were viewed as a *tabula rasa*. Karl Lorenz, the major founder of ethology, was the leading figure in this opposition to behaviorism.

American behaviorists did not deny the role of heredity, but it is true that they were slow in coming across with ethology. Skinner seems to have discovered it in the 1960s, and he discussed some of Lorenz's ideas in a paper entitled 'The phylogeny and ontogeny of behavior' (Skinner, 1966). He developed further his view in several writings. Briefly, he did not deny the evolutionary origin of many aspects of behavior, nor did he deny the species-specific differences derived from evolutionary history. Such denial would have been paradoxical from a scientist who proposed to extend the model of biological evolution to individual learning and to cultural history. He viewed his analysis of behavior and the ethological approach as complementary, not competing. It is fair to point that Lorenz later made steps in the same direction (Lorenz, 1981).

Radical Behaviorism

As a behaviorist, Skinner viewed psychology as a branch of natural sciences, more explicitly as a branch of biology, which can deal with its subject matter using the same principles as in other fields of life sciences, be it with specific implementations as required by its particular level of analysis.

Skinner defended a brand of behaviorism quite distinct from the dominant view that prevailed in the second quarter of the century. His radical behaviorism was opposed to methodological behaviorism. For most psychologists, defining their science as the science of behavior, after Watson's recommendation, did not really mean that they had abandoned mental life as the main objective of their inquiry; rather, they had simply resigned themselves to study behavior, because they had to admit that they had no direct access to mental life. Such methodological behaviorism, in fact, remained basically dualistic. In contrast, radical behaviorism is definitely monist,

and it rejects any distinction between what is called mental and behavioral. Skinner is, in this respect, closer to Watson's view than to the position of other influent neobehaviorists of his generation, although he developed a far more sophisticated view of behavior than Watson's. For instance, he rejected the simplistic claim that thought is nothing more than subvocal language, and admitted that not all behavior is directly observable. Part of human behavior is obviously private, or covert, and raises difficult methodological problems of accessibility; but this is no reason to give it different status in a scientific analysis.

Skinner vigorously denounced mentalism not so much because it refers to events that would occur in another space and be of a different substance than behavior, but because it offers pseudo-explanations which give the illusion of understanding what in fact remains to be accounted for. Mentalistic explanations, very common in daily life psychology, were still quite frequent in scientific psychology. For example, in the field of motivation, all sorts of behavior were assigned internal needs as causal agents: not only do we eat *because* we are hungry – a simple statement which, at any rate from a scientist's point of view, requires qualification – but we exhibit aggressive behavior because of some aggression drive, we interact with social partners because of a need for affiliation, we work to successful and creative outcomes because of a need for achievement, and so on. For Skinner, such explanations dispense us from looking for the variables really responsible for the behavior; these variables are more often than not to be found in the environment, and can be traced to the history of the individuals interacting with their environment, social and physical.

Combining this epistemological conception and the results of his empirical research, Skinner developed a theory of human behavior emphasizing the determining role of environmental contingencies on human actions. However, along the lines of the evolutionary analogy, he suggested a model that would account equally well for novelty and creative behavior, as exhibited in art and science productions, and for stabilized, persistent habits adapted to unchanging conditions.

Language and Consciousness

Skinner devoted special attention to verbal behavior, the importance of which in the human species justified special treatment. He presented his book *Verbal Behavior* as 'an essay in interpretation,' proposing a functional analysis of the verbal exchanges composing the global episode of speaker-listener communication. In spite of the violent criticisms expressed by the linguist Chomsky (1959), Skinner's analysis foreshadowed some aspects of the pragmatic approach adopted some years later by many psycholinguists, aware of the insufficiency of formal grammars to account for central features characterizing the use of language. He viewed verbal behavior as shaped by the linguistic community, and exerting a genuine type of control over an individual's behavior, distinct from the action of the physical environment. A large part of human behavior is, in his terms, rule governed, that is, controlled by words, rather than shaped by contingencies, that is, through direct exposure to the physical world. Many behaviors can have one or the other origin: avoidance of fire flame can derive from direct experience with fire, or from warnings received during education. Once endowed with verbal behavior, individuals can use it to describe and anticipate their own behavior, or to develop it in its own right, as in literary composition. Were it not for the unfortunate use of the term 'rule,' which makes for confusion, on one hand, with the word as used in formal linguistics and, on the other hand, with the notion of coercive control, what Skinner was pointing to was akin to a distinction now familiar to contemporary psychology and neurosciences between top-down versus bottom-up causation.

Given the widespread renewal of interest for the scientific study of consciousness in the last 25 years, it is appropriate to ask the question: What was Skinner's view on consciousness? More often than not, behaviorists have been blamed for rejecting the study of consciousness out of the field of scientific enquiry, and for having in fact imposed a taboo on the whole scientific community. Such opinion refers to the supposed negation of consciousness by Watson – while he simply denounced the methodological dead end of relying on conscious introspection in accounting for psychological reality. The alleged taboo has not prevented psychologists of various orientations from taking interest in conscious processes. Nor has it prevented members of the behaviorist school to do so, as was the case of Lashley, then in his behaviorist period, who published a long and important paper on the question (Lashley, 1923).

Be that as it may, Skinner was explicitly concerned with the problem of consciousness. He viewed it as a by-product of verbal activity shaped by the verbal community, providing individual speakers with tools for self-description and for reporting to others and to themselves their actions, feelings, and ideas. This approach is essentially similar with Vygotsky's thesis on the socio-discursive origin of consciousness, adopted and further elaborated by his followers, notably Luria. There is no evidence that Skinner was aware of the convergence with these Russian authors.

Also of interest in relation with the issue of consciousness is the discussion published in 1969 on the now very popular issue in Artificial Intelligence circles: could a machine be conscious? Skinner argues that "… the one currently irreducible difference between men and machines" is that: "They are built differently. The ultimate difference is in componentry … To be conscious or aware of itself as a man is conscious of himself a machine would have to be built like a man and would, of course, be a man." Far from ignoring consciousness, Skinner treated it recurrently with the attention it deserves in contemporary debates.

Education

Skinner's interests in applications covered three main areas: education, psychological treatment, and social practices at large. He dealt with the first two in a technical manner, developing principles and techniques for improving educational and therapeutic practices. His treatment of the third one is more akin to social philosophy than to scientific application, although he viewed it as very consistently rooted in his scientific thinking. At a time school education in the United States

was criticized for its deficiencies and for its inefficiency in competing with technological achievements of the Soviet Union, Skinner, as many other American scientists, inquired into the reasons of that state of affairs. Observing what was going on in any normal classroom, including in reputed schools, he concluded that it was violating blatantly most basic principles of learning derived from laboratory analysis of the learning process. Pupils and students were passively exposed to teachers' monologues rather than actively producing behaviors followed by feedback; there was no attempt to adjust the teacher's actions to individual level and rhythm of learning; negative evaluation based on mistakes and errors prevailed over positive evaluation pointing to progresses achieved; punitive controls, known to be poorly effective in shaping and maintaining complex behavior, were still widely used; general conditions and teaching practices were far from favorable to developing individual talents and creativity. Such criticisms had been made by others, but Skinner differed from them in the analysis of the causes and in the remedies proposed. He did not question the importance of endowing the students with basic knowledge and skills that they need if they are to engage in more complex and original activities. But he thought such skills could be mastered using more efficient methods than those currently in use in the classroom. This was the origin of teaching machines, a term that would raise strong objections on the ground that machines could not lead but to dehumanizing teaching. In fact, Skinner's idea has been implemented since then in computer-assisted learning, which is now widely accepted without any protest, but usually with little or no reference to the pioneering projects of the behaviorist psychologist. The device he designed in the 1950s appears quite primitive compared with modern computers: It was an electromechanical machine, adapted from a record player, built in such a way that it would present in a window to the student successive small frames of the material to be learned, each frame requiring an active answer from the learner. The latter could learn at his or her own individual rhythm, ideally with no or few errors, and eventually reach the end of the program, with the guarantee that the subject matter had been mastered from end to end. Good programs would make exams useless, if exams are just a way to control that the material has been covered and understood. Most important, student and teachers would not waste the few hours they could work together in tasks easily fulfilled using teaching devices; they could devote the time so spared to more constructive activities requiring direct human contact.

In spite of numerous attacks from educational circles, Skinner's project inspired many applications, such as programmed instruction in book form, until modern computers would offer the elegant solution we know today. It also contributed to the development of individualized teaching approaches that favor methods allowing students to learn at their own pace in an autonomous and active way.

Teaching machines are but one aspect of Skinner's contribution to education. In a number of his writings, including his utopian novel, Skinner (1968, 1978) did express his reflections on educational issues. He was concerned especially with the disproportion between the resources devoted to education and the poor outcomes; with the tendency to level down individual differences; with the increasing distance between the school environment and real life; with violence in schools, and other matters which remain crucial issues today, with little improvement.

Behavior Therapy

Treatment of psychological disturbances was another field of application to which Skinner (1955, 1989) made influent contributions. By the middle of the twentieth century, psychopathology had elaborated refined descriptive systems of psychological disturbances and equally sophisticated explanatory models such as the psychoanalytic theory. Contrasting with these, methods for treatment were scarce and their results poor. Psychoanalytic treatment had limited indications and practical limitations. Rogers's nondirective therapy, though quite popular, did not provide convincing results. Psychopharmacology was still in the air.

Skinner did not question the classical categorization of mental illnesses, nor did he propose miracle remedies. He simply suggested to look at them as disturbances in behavior, rather than alterations of hypothetical mental structures, such as the psychic apparatus appealed to by psychoanalysis, of which abnormal behavior would be but observable indicators, or symptoms. Consequently, he proposed to attempt to change undesirable behavior by acting directly upon it, rather than upon underlying structures supposedly responsible for it. This approach was not totally new: behavior therapy had its origins in John Broadus Watson's attempts to treat fear in children by resorting to Pavlovian conditioning and in the theoretical work of some neobehaviorists aimed at transposing some psychoanalytical concepts into learning theory models. What Skinner added was his genuine theoretical elaboration, especially based on his antimentalist stand, and techniques of behavior modification drawn from the operant laboratory, supplementing Pavlovian techniques in use up to then. He also brought into the clinical field a sense of rigor transferred from the laboratory, perfectly compatible with the study of single cases.

Skinner did not practice behavior therapy himself. His influence in the field was indirect, by stimulating pioneering research on psychotic patients and mentally deficient people. He gave a decisive impulse to the development of the behavioral approach to treatment, which soon acquired a major position in clinical psychology and counseling, and which eventually merged with cognitively oriented practices into what are labeled cognitive-behavioral therapies. This appears as a somewhat paradoxical evolution given Skinner's opposition to cognitivism. It suggests that practitioners, being professionally more pragmatic, have perceived complementarities between the two schools of thought rather than sticking to doctrinal divergences. Cognitive-behavioral therapies, claiming their evidence-based status, have gained an important share in psychotherapeutic practices around the world, supplanting psychoanalytically oriented treatments. However, their success varies depending upon the country. For example, on the European continent, while they have been widely accepted in most West countries, cognitive-behavioral therapies have been strongly opposed by a typically French

psychoanalytic tradition, in a conflict with institutional and even political implications.

Social Philosophy

Skinner's social philosophy was rooted in a deep confidence that only science would help us in solving the problems we are facing in our modern societies. What is needed is a science of behavior, which in fact is now available, he thought, and could be applied if only we would be ready to abandon traditional views of human nature. He first expressed his ideas in the novel *Walden Two* (1948). Written 2 years after the end of the World War II, the book describes a utopian community run after the principles derived from the psychological laboratory. It is by no means a totalitarian society, as some critics have claimed. Looked at retrospectively, it is surprisingly premonitory of social issues that are still largely unsolved more than half a century later. For instance, working schedules at *Walden Two* have been arranged so that all tasks needed for production of goods and good functioning of the community are distributed among members according to a credit system which results in an average amount of 24 h per week, avoiding unemployment, abolishing any social discrimination between manual and intellectual work, and leaving many free hours for leisure activities such as sports, arts, and scientific research. Emphasis is put on active practice rather than passive watching, on cooperation rather than competition. The community is not isolated culturally: cultural products from outside such as books or records are of course welcome, but radio programs are filtered to eliminate publicity. Education is active; the school building symbolically has no door separating it from the life and work community; there are no age classes, no humiliating ranking; all learn at their own rhythm, in whatever orientation they feel appropriate, throughout their lifetime. Women enjoy complete equality with men. Waste of natural resources is avoided. Special charges in the management of the community are strictly limited in time, eliminating any risk of political career.

The utopian novel has been for the author the occasion to discuss the practice of democracy, also dealt with in a number of his other writings. He denounced the counterproductive effects of the race or fight for power, generating excessive personalization of politics; the tendency of politicians to reject the responsibility of their failures on the citizens who had elected them; the lack of concern for minorities. By the time of the immediate after World War II, when he was writing *Walden II*, he lucidly qualified the process of election of the presidents of the United States as a "masquerade of democracy." He demystified the subtle ways politicians do mask the control exerted over people and he insisted on the importance of developing appropriate strategies of countercontrol.

Similar themes, plus the frightening concerns with pollution, violence, uncontrolled population growth, nuclear weapons, and the like, are further elaborated in the book *Beyond Freedom and Dignity* (1971) and a number of later articles. In an alarming tone, Skinner points to what he feels is the core of our inability to deal with these issues, that is our obstinacy in keeping a conception of human nature which scientific inquiry shows us to be wrong, and which bars any solution to the problems we are confronted with. We still stick to a view of humans as being the center of the universe, free and autonomous, dominating nature, while we are but one among many elements of nature. As a species, we are the product of biological evolution; as cultural groups, the result of our history; and as individuals the outcome of our interactions with the environment. Because we fail to admit this dependency, and draw the consequences of it, we might put in danger our own future. Freedom, autonomy, and merit are no absolute values: They were forged throughout history, and more often than not they are used to disguise insidious controls, the mechanisms of which should be elucidated if we want to develop countercontrols eventually allowing for the survival of our species.

Skinner and Other Great Contributors to Psychology of His Time

Skinner viewed these various facets of his work as closely related, making for a highly consistent theory of human behavior, in which the critical analysis of social processes in modern society was deeply rooted in the experimental analysis of the behavior of animal subjects in the laboratory. So global an ambition has been criticized, and clearly various aspects of his contribution did not have the same fate. If the operant technique is now a widely used procedure to many purposes in experimental research in psychology and related fields, if his early attempts to build teaching machines appear now as ancestors of computer-assisted learning and teaching, if a number of principles of contingencies analysis are now currently put in practice in behavior therapies, radical behaviorism has been seriously questioned and even shaken by the rise of the cognitivist approach in psychology, while Skinner's social philosophy has been attacked from different fronts both on ideological and scientific grounds.

As most great theory builders of the twentieth century in psychology, from Sigmund Freud and Watson to Jean Piaget, Skinner may be blamed for having reduced the explanation of human nature to a very limited set of concepts and findings, namely those he had forged and observed in his own restricted field of research and reflection, ignoring even other concepts and facts in neighboring fields of psychology, leaving alone of other sciences. It is clear that Skinner has made no attempt at integrating, for example, contributions of developmental or of social psychology, nor those of sociology, cultural anthropology, or linguistics. Such neglects might have been deliberate, legitimated by the will to concentrate on what were, in Skinner's mind, essential points left out by other branches of psychology or other sciences dealing with human societies. However, they might appear as sectarianism to those who favor an integrative and pluridisciplinary approach to the complex objects of human sciences. It cannot be decided whether his influence would have been larger or smaller had he adopted a less exclusive stand.

Abstract

Theda Skocpol, currently the Victor S. Thomas Professor of Government and Sociology at Harvard University, analyzes and researches the principal historical transformations of society. Skocpol's work is an exemplar of historical comparative research. She has asked, and of course answered, 'big' questions: What are the causes of social revolutions? Why has the United States welfare state developed as it has? What is happening to American civic life and democracy? These three questions have guided the three distinct yet overlapping tracks Skocpol's research has followed. The answers proffered by Skocpol and the concepts she developed and deployed to do so, causal historical analysis, state and polity autonomy, policy feedback, and diminished democracy, are described and discussed.

In a 2013 interview for Salon, an online political news magazine, Skocpol is asked a number of questions regarding the current state of politics in the United States. This interview is notable, not because of its social scientific contribution, but because of Skocpol's continued ubiquitous presence in the United States' political public sphere. Skocpol, currently the Victor S. Thomas Professor of Government and Sociology at Harvard University, is an exemplary and unique scholar that has contributed in a multitude of ways to a variety of disciplines, including Sociology, Political Science, and History, a variety of subfields including historical comparative analysis, comparative politics, and political sociology, and has had a palpable and important influence in public discussions. In this particular interview, Skocpol touches on the most important currents in her intellectual trajectory. That is, state autonomy, the history of U.S. social policy, and the structures and institutions of U.S. democratic practice.

Skocpol has addressed these disciplines, subfields, and concepts in 23 books and edited volumes as well as over 70 academic articles. Her pioneering book on social revolutions, *States and Social Revolutions: A Comparative Analysis of France, Russia and China*, is the most influential sociological analysis of revolutions to date. It is also where she first and most poignantly advances her theory of state autonomy. She followed this watershed book with the epic historical comparative account of the United States welfare state in *Protecting Soldiers and Mothers: The Political Origins of Social Policy in the United States*. Here Skocpol continues to advance her historical comparative method in conjunction with her focus on state autonomy. Since the publication of *Protecting Soldiers and Mothers*, Skocpol has furthered her academic reach by entering into the discussions surrounding civic engagement and declining democracy in the United States. Her book *Diminished Democracy: From Membership to Management in American Civic Life* challenges academic, and popular, arguments alike about the decline of citizen engagement. More recently Skocpol has continued to fortify her intellectual program on U.S. politics through research on health care policy (*Boomerang: Clinton's Health Security Effort and the Turn Against Government in U.S. Politics* and *Health Care Reform and American Politics: What Everyone Needs to Know*), Obama's presidency (*Obama and America's Political Future*), and the rise of the 'Tea Party' (*The Tea Party and the Remaking of Republican Conservatism*).

Theda Skocpol has had a fascinating life and early career. She was born in Detroit, Michigan. She received her undergraduate degree in sociology from Michigan State University. During her time at Michigan State, she worked with a civil rights education project at Rust College in Holly Springs, Mississippi. While working on this project she met her husband Bill Skocpol. Skocpol was deeply influenced by the political environment engulfing American campuses during the 1960s and 1970s (Weir, 2002). After graduating from Michigan State in 1969, she attended Harvard University where she studied with Barrington Moore Jr. (author of the groundbreaking work *The Social Origins of Dictatorship and Democracy*). She graduated from Harvard with her PhD in Sociology in 1975. Following the completion of her PhD, Skocpol became a professor of Sociology at Harvard University. She occupied this position from 1975 to 1981.

In 1980 Skocpol was up for tenure at Harvard University. After a five-to-five vote by the tenure committee, with one abstention, the department decided to deny Skocpol tenure. She would have been Harvard University's first female tenured sociology professor (Schumer, 1981). Skocpol, who had just won the American Sociological Association Award for a Distinguished Contribution to Scholarship for *States and Social Revolutions*, filed a suit of sex discrimination against the department and left for a tenured position at the University of Chicago. She remained at Chicago for 5 years and during that time an internal review at Harvard deemed that discrimination was in fact the cause for Skocpol's tenure denial. In 1986 Harvard offered Skocpol tenure and she returned to be the first tenured female sociology professor at Harvard.

Skocpol has had vast and prolific influence on the fields of sociology, political science, and American politics. In 1998 Skocpol became the Victor S. Thomas Professor of Government and Sociology at Harvard University. From 2000 to 2006, she was the director of Harvard's Center for American Political Studies. And, from 2005 to 2007, she was the dean of Harvard's graduate school of arts and sciences. She has received a number of awards for her work and her career achievements, and in 2007 she received the prestigious Johan Skytte Prize in Political Science.

For contemporary scholars working on the broad topics of states, politics, and historical and societal change, engaging Theda Skocpol's work is imperative. Following from the founders of sociology, Marx, Weber, and Durkheim, Skocpol has been interested in the principal historical transformations of society. Skocpol's work is an exemplar of historical comparative research. She has asked, and of course answered, 'big' questions: What are the causes of social revolutions? Why has the United States welfare state developed as it has? What is happening to American civic life and democracy? These three questions have guided the three distinct yet overlapping tracks Skocpol's research has followed.

What Are the Causes of Social Revolutions?

Skocpol's dissertation addressed what she deemed as problems existent in the scholarship analyzing revolutions. The book that resulted from her dissertation was *States and Social Revolutions*. In this book, Skocpol powerfully maps out the causes of the social revolutions in France, Russia, and China and convincingly argues that comparative historical analysis "is the appropriate way to develop explanations of revolutions that are at once historically grounded and generalizable beyond unique cases" (1979: p. 6). She accomplishes this through comparing, what she proffers as three similar or 'positive' cases, France, Russia, and China, and by comparing these cases to a variety of 'negative' cases. That is, cases that have similar causal variables and sequences but do not have similar results (in particular Russia 1905, Japan, Germany, and England).

To best clarify the appropriate cases under investigation, Skocpol clearly conceptualizes social revolutions. Skocpol defines social revolutions as the occurrence of societal structural change with class upheaval, and the occurrence of political with social transformation. She distinguishes social revolutions from political revolutions and rebellions. Political revolutions "transform state structures but not social structures, and they are not necessarily accomplished through class conflict." Rebellions, "may involve the revolt of subordinate classes [even when successful] but they do not eventuate in structural change" (p. 4). In this way, Skocpol can analyze the "relatively few historical instances" of social revolution with specificity and generalizability. Using positive and negative cases of comparison, we glean what variables are existent during successful revolutions that are not during failed social revolutions, political transformations, or rebellions.

Skocpol was discontented with the trends she had read in the current theory regarding revolutions. The theories existent on revolutions fell into two camps: the Marxist and the pluralist. Skocpol correctly highlights the disconnect present between theory and history within these two theoretical trajectories. She further quashes each of these approaches as they fall short of truly understanding the amalgamation of variables involved in creating the conditions for a successful social revolution. As Skocpol highlights, the leading models for understanding revolution all follow a similar, but misguided, pattern. That is, changes give rise to grievances and disorientation, which leads to a conscious and 'purposive, mass-based movement.' This movement "fights it out with … the dominant class and, if it wins, undertakes to establish its own authority" (pp. 14–15). Skocpol argues that this analysis is reductionistic especially in regard to its emphasis on a 'voluntarist' understanding of revolutions. Skocpol does not completely shunt aside ideological or cultural claims (see pp. 164–171) and she returns to them in 1994 in *Social Revolutions in the Modern World* (see pp. 199–210). However, in part because her analysis is on the macroscopic level, she dismisses an ideological perspective for a nonvoluntarist or nonintentionalist historically grounded structural approach.

Skocpol considers the constellation and sequence of contingent variables at work creating the conditions for a successful social revolution. These variables consist of the structural conditions of the old regime, intranational conflicts, international structures and world historical conditions, and the structure of the institutional apparatus known as the state. Prevailing theories of revolution, at that time, according to Skocpol, focused exclusively on intranational conflict, and reduced the state to a puppet of dominant class interests (Marxists) or as a representation of liberal society (pluralists). Skocpol, on the other hand, argues that the state is a potentially autonomous structure. The state has a logic and interests of its own that are 'not necessarily equivalent or fused with' the dominant class or 'the full set of member groups in the polity' (p. 27). This theoretical and empirical advance over past understandings of social revolutions has inspired a spate of research interested in the state as an autonomous actor (Skocpol, 1985).

In the end, Skocpol finds that revolutions are a three-stage process that happens in three short time periods. First, old regime states are weakened by international conflict in the form of military defeats or economic crises. The former simultaneously discredits rulers and makes them appear vulnerable. The latter upsets elites, who are dependent upon a strong state for their income, as well as the masses, who face deprivation and increases in taxes as the state attempts to generate new revenues. Second, the operation of the old regime's state apparatus is disrupted by elites and masses with impunity. Last, the old regime is killed or forced into exile and the new regime obtains the position of power (see Lachmann, 2013 Chapter 3 for an excellent survey and comparison of Skocpol's methods).

States and Social Revolutions was and remains an exceptional piece of scholarship that has had wide-reaching influence. It was cited as among the most influential books in sociology and political science in 1996, 17 years after its publication. It has been translated into nine different languages. It has inspired a deluge of research on revolutions and is the exemplar for the utilization of comparative historical analysis. Inspired by this work and an increasing desire to re-cement historical comparative methods in sociology, Skocpol wrote, with Margaret Somers, "The Uses of Comparative History in Macrosocial Inquiry" and edited a book titled *Vision and Method in Historical Sociology* (1984). Skocpol, also, coedited the book *Bringing the State Back In* (1985), where you can find some of the research deeply influenced by the theoretical and empirical thrust of the state-centered analysis exemplified in *States and Social Revolutions*. In *Bringing the State Back In*, you can also find Skocpol's programmatic title piece. Equipped with the methods and concepts developed and deployed in her work on social revolutions, Skocpol shifts her attention to the history of United States social policy.

Why Has the United States Welfare State Developed as It Has?

Skocpol's work following *States and Social Revolutions*, beginning in the 1980s, focused on understanding public social policies in the United States. Her contributions in this field have inspired and influenced debates in a similar manner as her earlier work on social revolutions. The first book she published answering questions about the United States welfare state and social policy was a coedited volume (with Margret Weir and Ann Shola Orloff) titled *The Politics of Social Policy in the United States* (1985). In this volume Skocpol and her colleagues further their discussion of the fruitfulness of the state-centered approach in determining what, why, and when policies get implemented. Following this edited volume, Skocpol published, *Protecting Soldiers and Mothers*, her epic analysis of the United States welfare state.

In *Protecting Soldiers and Mothers* (1992), Skocpol links Civil War pensions to the conditions of nineteenth century American politics and then to the reaction against such polices in the progressive era. She focuses her analytical and empirical attention to the conditions with which particular social policies passed or were defeated. Once again, Skocpol is attuned to the complex constellation of variables at work and is interested in debunking the idea, proffered in popular and scholarly perceptions alike, that generous social provisions were suddenly created in response to the great depression era. "At that point, most scholars presume that the United States joined the evolutionary mainstream of western social progress – as a 'laggard' on the universal road toward 'the modern welfare state'" (p. 4). This explanation, according to Skocpol, for what social policies are passed at particular times and defeated at others is tenuous at best. Dissatisfied with current research trends, Skocpol rejects the problematic premise that they all share "about the evolutionary nature of 'the welfare state' and the socioeconomic roots of political processes" (p. 39). Elucidating the state as an autonomous actor in the process and struggle for control over policy implementation, Skocpol argues, we do not fall prey to this same a priori trap.

The sociological puzzle to be pieced together is represented by this question: why did the United States not develop similar welfare states as their European counterparts? Utilizing 'European welfare states' for comparison, Skocpol finds that the United States Civil War pensions at first were, indeed, modest. However, during the time period of 1879–1906 social benefits were traveling toward a 'paternalist' state representing magnanimous social benefits for veterans and the elderly. During this historical moment, the trend of American politics toward 'paternalist' policies did not 'lag' behind their European counterparts. In fact, these provisions, as Skocpol demonstrates, accounted for 41.5% of the federal budget by 1893. Following this time period, however, a shift in the social benefit provisions occurred. Due in part to the perceived corruption by politicians and reformers of these provisions, Civil War pensions did not germinate. Alternatively, they became a warning sign for future similar policies. Skocpol argues that United States social policy then became, in large part because of women's civic associations, a 'maternalist' state. By the 1920s, however, these provisions also lost steam and the United States never "quite crystallized into a full fledged maternalist welfare state" (p. 534).

Three of the historically grounded conceptual ideas, that have had extensive influence, present in *Protecting Soldiers and Mothers* should be highlighted: state autonomy (polity autonomy), policy feedback, and the impact of women's civic associations. First, not surprisingly, Skocpol finds much of the causal activity in the process of policymaking in the state. She broadens her state-centered analysis to more effectively include all "political activities whether carried out by politicians or social groups" (p. 41). She terms this a "polity-centered approach." Political activities are, in congruence with the state-centered approach, "conditioned by the institutional configurations of governments and political party systems" (p. 41). Second, the concept of policy feedback highlights Skocpol's emphasis on historical and political contingency. That is, policies are not only a dependent variable but once instated they have independent causal thrust. A historical comparative framework will have to understand that the introduction of particular policies impacts future policy and political trajectories. This concept was utilized previously by Orloff and Skocpol (1984) and discussed by Skocpol and Amenta (1986).

Third, Skocpol brings much needed attention to the role women's civic association played in the development of a 'maternalist' welfare state in the United States during the early twentieth century. For Skocpol, the deficient development of social politics for American men, when compared to European welfare states and American women, can be historically traced to "federated white women's clubs" (1992: p. 26). Dissimilar to American men reformers, who only took their case to a limited circle of elite legislators, women built a coalition from the ground up. Grassroots organizations that mobilized cross-class coalitions, encompassing 'upper and middle class women, joined by some wives of skilled workers,' were exceptionally successful during a short period of time at the turn of the twentieth century (p. 51). Unlike their male counterparts, Skocpol argues, women in their fight for suffrage created the structural seeds for mobilization. "Tying together clubs based in local legislative districts into statewide and nationwide networks of social communication … these widespread associations were well situated to promote specific kinds of social policies" (p. 56). These policies were embodied by 'maternalist' ideals. The emphasis Skocpol placed on marginal groups,' in this case women, historical influence on policymaking processes was pioneering. The analysis of the state institution and policy feedbacks continued Skocpol's insights on elites who affect policy formation. The addition, and impact found, of women's civic associations adds veracity to the process of policymaking and foreshadows Skocpol's future research projects on civic associations.

Skocpol continues her analysis of the failure of the United States to introduce national social insurance programs in her more recent work in *Boomerang* (1997a), *Health Care Reform and American Politics* (2010), and *Obama and America's Political Future* (2012). In *Boomerang*, Skocpol traces the political and state-oriented constraints that the Clinton administration navigated unsuccessfully. The popular presumption about the 'stupidity' amongst the Clinton administration or the fickleness of American public opinion was not the cause of Clinton's health care failure. Rather, Skocpol focuses our attention on the structure and constraints of the state and the political environment. In the end, as Skocpol demonstrates, the political

repulsion of the signifier 'taxes,' the report of the Congressional Budget Office (CBO) and the decisive power of private insurance firms blocked the Clinton health care bill and created a reaction against government. Jacobs and Skocpol continue this line of thought in *Health Care Reform and America Politics*. They describe the policy feedback mechanisms of a failed Clinton plan's influence on the construction of Obama's Affordable Care Act. In the end, Obama's legislation, according to Jacobs and Skocpol, was the result of a "chain of contingent events that transformed the relationship among physicians, hospitals and insurance companies, and thereby shaped each of those groups' interests and their capacities to act politically alone or in alliance with others" (Lachmann, 2013).

Further research on national insurance programs in the United States is conducted in the book *Obama and America's Political Future* (written by Skocpol with commentaries by Larry M. Bartels, Mickey Edwards, and Suzanne Mettler). The incipient objective of *Protecting Soldiers and Mothers* was to understand New Deal policies in American politics (pp. vii–ix). That book transformed into an exploration of policymaking prior to the New Deal that necessarily brought women to the forefront of historical policy research. The original goal, however, was returned to in her essay "Obama's New Deal, Tea Party Reaction, and America's Political Future" in the book *Obama and America's Political Future*. Obama ran and won in 2008 on the grounds of passing new legislation with similar ideals to Franklin D. Roosevelt (FDR) in his New Deal era. In her essay Skocpol, consistent with her historical comparative analysis, compares Obama's first years in office to FDR's. Skocpol proffers that the timing of the economic downturn, the structure of party polarization, the volatility of the media institution, policy feedback mechanisms and backlash in the form of the emergence of conservatism represented by the Tea Party, created the conditions for Obama's more modest accomplishments (More specifically, Skocpol proffers five reasons for Obama's more modest accomplishments. First, unlike FDR and Hoover, Obama necessarily, because his economic downturn was at an earlier stage, had to cooperate with George W. Bush and his economic advisors. Second, the polarized structure of American politics for Obama was different from FDR's time. Polarization, for Obama, is structured purely along party lines. Experts, therefore, on the opposite side of the political spectrum, that knew the economic downturn would continue, had no desire to make concessions. Third, the structure of the media was in, and still is in, the midst of a massive transformation represented by increasingly successful openly aligned partisan media outlets and economic turmoil. These changes increase complications for a president trying to navigate such a volatile terrain. Fourth, FDR built his policies anew, while Obama, on the other hand, unavoidably had to redirect existing path-dependent government institutions and path-dependent policies. Finally, in part due to the new structure of partisan media, is the emergence of a political opposition, similar to the civic associations of America's past, called the Tea Party (Skocpol and Jacobs, 2011).).

In order to answer questions regarding the United States welfare state, Skocpol necessarily elucidated the complexities of historical contingencies. *Protecting Soldiers and Mothers* demonstrated that universal welfare states do not develop in an evolutionary process. Instead, particular policies, during particular historical moments, are constrained by the structure, relationship, and interaction between a variety of political actors. Comparable to social revolutions, social policies are created when an opening in the state structure coincides with the political action of civic associations, as exemplified by the maternalist policies enacted at the turn of the twentieth century. Health care policy tells the opposite side of this story. Skocpol, inspired by her work on women's civic associations, continued down this road and began thinking about her most recent question.

What Is Happening to American Civic Life and Democracy?

For analytical purposes I have separated this article into three sections representing three distinct questions that Skocpol has answered throughout her career. These three trajectories, however, have overlapped empirically, as are exemplified by the emphasis on women's civic associations in *Protecting Soldiers and Mothers* and the discussion of the contemporary civic associations such as the Tea Party in *Obama and America's Political Future*. Skocpol's influential work on civic engagement deserves some independent attention. In 1999 Skocpol coedited *Civic Engagement in American Democracy*. In this book Skocpol wrote the chapter "Advocates without Members: The Recent Transformation of American Civic Life." In this article Skocpol carefully crafts the alterations occurring in the organization of American civic life. Following this she wrote *Diminished Democracy* (2003). In this book, Skocpol highlights, using primary historical documents, the changes in the institutional structure of civic associations in the United States over a century. Her analysis on American civic engagement, which represents a major progression from the existent literature, is twofold. First, she wants to understand civic decline and diminished democracy and second, consistent with all of her other research tracks, she wants to understand how civic associations in civil society can enact political power and potentially get social policies passed.

Observing the trends in American civic engagement has a long history. Tocqueville was first enamored with American's propensity toward joining civic associations in civil society in the 1830s. Skocpol (1997c) enters into this debate armed with historical insight and evidence to add much needed sophistication. She finds that nearly two-thirds of the largest civic associations in the 1950s, though claiming nonpartisanship, 'were directly involved in legislative campaigns' or political efforts of some sort (Skocpol, 2003: pp. 26–30). Further, members joined local chapters of associations for a myriad of reasons, often including social, not political, benefits. Skocpol argues that this empirical fact is important to democracy. Members active in local chapters learned important democratic skills including "how to run meetings, handle moneys, keep records, …participate in group discussions" and recruit new members. Moreover, with the democratic skills learned in these local chapters members could "move up to responsibilities at the district, state and national levels" (Skocpol, 2011: p. 115).

These civic associations with their federated structure, Skocpol finds, were "highly effective at mobilizing members across the nation to lobby for government programs that

addressed concerns that members raised at the local level" (Lachmann, 2010: p. 153). The political prowess of these types of civic associations is exemplified by the America Legion's successful push for the inclusive and magnanimous legislation represented by the G.I. Bill. Skocpol analyzes the contingent and historical variables at work in the process with which this bill was passed in her article "The G.I. Bill U.S. Social Policy, Past and Future" (1997b). In this article she also discusses the concept of policy feedback to highlight the impact the G.I. Bill has had and will continue to have on future policy possibilities in the United States.

During the twentieth century, however, Skocpol and other scholars (see Putnam, 2000) began observing a decrease in engagement, demonstrated by the dissipation of American civic associations. Skocpol finds that up until the early 1960s Americans were ardent joiners and members of civic associations, especially when compared to their European counterparts. Skocpol brings our attention, diverging from previous scholarship, to the "rapid civic reorganization between the mid 1960s and the early 1990s during which elite, well-educated Americans abandoned cross-class membership federations while launching professionally managed organizations" (Skocpol proffers four reasons for this civic transformation. First, unlike the Civil War, WWI, or WWII, the Vietnam War did not inspire the same fraternity among veterans. Second, the civil and human rights revolutions of the 1960s and 1970s challenged the historical gender roles and racial divides characteristic of past civic associations. Thus, "younger generations were reluctant to join" (Putnam, 2000). Third, as women entered the workforce they were no longer available to cater and work to keep the traditional male civic associations afloat. Fourth, emphasizing state autonomy the government entered into a variety of realms of social life fostering the opportunity for a deluge of new professionally run civic associations.) (Skocpol, 2003, 2011).

Professionally run civic associations are organized in a much different way than those previously prominent. These organizations are not structured as national federations with local chapters. Rather these associations are elite-run advocacy groups utilizing the availability of new technology to administer massive mailings and phone calls. Instead of vibrant local chapters with dues paying members these new associations hinge on a large membership of check senders (Skocpol, 1999, 2003). New professional associations are often elite-run and not intraclass, one of the most important characteristics of the old associations. These professional organizations are not conducive to democratic participation; rather they take the power out of the hands of everyday citizens and place them in the hands of elites. This historical context, the professionalization of civic associations is, according to Skocpol, the major example of diminished democracy.

Skocpol, in her coedited volume (with Lawrence R. Jacobs) *Inequality and American Democracy: What We Know and What We Need to Learn*, addresses the impact this structural transformation of civic engagement has on inequality. Skocpol argues that because experts are more valued and paid, and professionally run advocacy groups only need citizen money to run effectively, there is no need for regular citizens to participate. Second, "because higher-educated Americans have experienced sharply rising incomes in recent decades, they are also the folks who can afford to pay for professionally managed advocacy efforts" (Skocpol, 2004, 2011: p. 116). Historically, popular civic associations that were cross-class advocated for 'inclusive' social policies. Skocpol suggests that there is no reason to think that the new professionally run groups will continue this trend. Thus, Skocpol argues, the structural alterations in civic life have not only diminished democracy but also have increased inequality.

Recognizing an anomaly in the shift toward professionally run advocacy groups in civil society, Skocpol turned her analytical gaze toward the Tea Party. Skocpol with Vanessa Williams, in their book *The Tea Party and the Remaking of Republican Conservatism*, analyze historical and demographic data in conjunction with interview research on the Tea Party they conducted. They find that there are around 900 local Tea Party chapters around the country. Their analysis demonstrates that these are organizations consisting mostly of concerned older white citizens. The issues these citizens underscore are the undeserving 'freeloaders' and immigrants who have not 'earned public support' (2012: pp. 60–68). This, however, does not capture the entirety of the Tea Party. Professionally run advocacy groups that existed prior to the emergence of the Tea Party in 2009 joined forces with the grassroots organizations. The combination of an old civic association and new professionally run advocacy groups, Skocpol argues, has given, and will continue to give, the Tea Party power to elect congruent political officials and impact the process of policymaking in the United States.

Skocpol's research recognizes the complexities of American civic engagement and democracy. Through a historical paradigm consistently attuned to comparison, Skocpol is able to fine-tune and clarify our understanding of the constraints and effects the structure of states and institutions can have on civic engagement and democracy. Simultaneously, Skocpol's analysis is able to illuminate the impact citizens can have on political processes. Skocpol understands that in order to unravel the intricacies of American politics, or the causes of social revolution, elucidating both of these variable sequences is imperative.

Three Tracks, One Goal

Theda Skocpol was not afraid to confront the principal questions of society. In her career she addressed three of the most important questions concerning sociologists, political scientists, and historians alike. These three questions sent Skocpol down three distinct yet overlapping empirical and analytical tracks. Utilizing historical comparative methods, while following all three of these tracks, Skocpol has consistently demonstrated the fruits of an institutionally grounded macro historical sociology. Her influence on the disciplines of sociology, political science, and history is momentous. It must not be forgotten, however, that Skocpol's influence has stretched well beyond academic walls. Any scholar or politician interested in the vicissitudes of political institutions and policies would do well learning from Skocpol's intellectual cannon.

Skocpol's work is and should continue to be a template of rigorous, robust, historically grounded, theoretically engaged scholarship. Her historical comparative analysis is unique in

its depth and breadth. The concepts developed and deployed in her work, causal historical analysis, state and polity autonomy, policy feedback, and diminished democracy have inspired a flood of future scholarship. Her overarching goal is to understand and connect the conflicts existent in historically grounded institutional structures in order to decipher crucial political outcomes. Understanding Skocpol's work is imperative for a practitioner from any discipline studying revolution, social policies, civic engagement, or democracy.

Slavery and Violence

Abstract

Throughout history, slavery has always been associated with violence. Following the different stages of the slavery experience, it is possible to focus first on the process of enslavement as a violent practice either resulting from warfare or from slave trades, from antiquity through the medieval and modern periods. Then, it is important to look specifically at historical forms of domination and control of the slaves and at the slaves' attempts to resist the violence of slavery through violent acts of resistance and rebellion. In most cases, though, the end of slavery came as a result of pressure brought upon governments by abolitionist movements and by other factors, with the consequent implementation of decrees sanctioning the peaceful transition to emancipation.

Introduction

As a violent system of exploitation and oppression, slavery has always been connected with violence throughout its long history. Scholarly studies on slavery have attempted to define the exact characteristics of the type of violence at the heart of slavery. Notably, Orlando Patterson, in his seminal monograph *Slavery and Social Death* (1982), has compared a range of societies across times and continents, where slavery was present in different shapes and degrees, and has formulated the now famous definition of slavery as "the permanent, violent domination of natally alienated and generally dishonoured persons" (Patterson, 1982: 13). In other words, for Patterson and for most slavery scholars, who followed in his path, the violence of slavery focused specifically on the characteristics of violent domination over individuals who had been uprooted through the process of enslavement and who were kept isolated, or alienated, as if they were reduced to an extension of their owners, in a state of symbolic 'social death.' Therefore, in order to investigate the constituent elements of the complex relationship between slavery and violence as it developed through history, we need to look first at the violent process of enslavement, and then at the types of masters' actual domination and control, and the consequent resistance, violent and nonviolent, to both by the slaves.

Historical Processes of Enslavement

Throughout history, the experience of slavery began in the most violent possible way for slaves with the trauma associated to the experience of enslavement. The violent process of uprootedness at the heart of the trauma of enslavement – which, for Joseph C. Miller, was a direct consequence of the dynamic process and historicized strategy of 'slaving,' or of mobilizing directly controlled human resources – left slaves helpless, violated, and vulnerable (Miller, 2011). In antiquity, the most common form of violent enslavement was through warfare. All the great powers of the ancient world, beginning from ancient Egypt and the Mesopotamian civilizations and ending with classical Greece and Rome, engaged in mass enslavement as a common practice related to warfare and conquest. The largest numbers of enslaved enemies could be found among the captives of great expansionist empires, such as, for example, Assyria, and, on an even larger scale, ancient Rome. Through relentless warfare and conquest, the Roman Republic and then the Roman Empire created a slave system with a flourishing slave trade and ubiquitous markets for the sale of slaves, which encompassed the entire Mediterranean area – effectively, the largest slave system in premodern times. At the height of Rome's expansionist period, Roman armies were able to enslave half a million people every year, so that, by imperial times, 10–15% of the whole population of the Roman Empire (50–100 million people) were enslaved; in Italy alone, as much as 30–40% of the population was made of slaves (McKeown, 2011).

Warfare continued to be the main cause of enslavement also throughout the medieval period. Often, violent enslavement was a direct consequence of the conquest and capture of enemies of a different religion; while Muslims had no qualms about enslaving Christians, Christians, in turn, routinely enslaved practitioners of Islam. A number of both regional and long-distance slave trades flourished in different areas of Europe and the Mediterranean, where slave markets could be found in all the main cities, showing that the business of capturing, selling, and purchasing slaves was a flourishing one during the entire Middle Ages. However, in northern regions, especially in northwestern Europe, between the thirteenth and the fourteenth centuries, slavery was gradually replaced by serfdom, while in eastern and southern Europe it went on for longer. While regions of eastern Europe, such as the borderland Slavic areas and the Black Sea coasts, supplied large numbers of slaves at least until the 1500s, during the same period both Italy and Spain witnessed the flourishing of a long-distance slave trade of Africans practiced by both Christians and Muslims in the Mediterranean (Phillips, 1985). With the quickening of pace in Ottoman expansion, in the 1500s and 1600s, the Christian–Muslim conflict in the Mediterranean resulted in massive enslavement of thousands of Europeans by the Barbary Coast corsairs, who conducted their raids from their bases in Algiers and Tunis; according to Seymour Drescher, in the period 1580–1680 alone, "an average of 7000 Christian captives per year were enslaved in the Maghreb," in North Africa. Most of the enslaved captives were Spanish, Portuguese,

French, and English, and these nations responded in kind by conducting raids for the purpose of enslaving North African Muslims throughout this century and afterward (Drescher, 2009: 28).

Starting from the mid-1400s, for four centuries, Europeans removed forcibly and violently from the West Coast of Africa more than 12 million people for the purpose of transporting them to labor on slave plantations in the New World. Succeeding one another in the control of sections of the Atlantic Ocean, partly relying on preexisting African traditions of slavery, partly creating the preconditions for the rise of African states trading in slaves, and mostly simply kidnapping and uprooting Africans of different ethnicities – particularly in the Gulf of Guinea, in the Gold Coast and Ivory Coast, in Senegambia, and in Angola – Europeans of different nations took the violent practices of enslavement and slave trade to an all-time high (Blackburn, 1997). First the Spanish and Portuguese, then the Dutch and the French, and ultimately the British, the Americans, and the Brazilians engaged in a lucrative forced transportation of slaves through the Atlantic – the 'middle passage' (a common expression used to describe the Atlantic slave trade from Africa to the Americas) – that caused close to 2 million deaths by the time Spain's slave trade, the last one operating, was definitely abolished in 1867. Whichever European power captured them, and whichever final destination in the Americas they were bound to, for all African slaves the 'middle passage' was a horrific ordeal, coming after the already extremely violent and traumatic experiences of being kidnapped, sold, and enslaved. Crammed in the belly of the ships so as to occupy all the available space, chained to one another in 0.5-m-high decks, slaves were left in the dirt for a period that often reached 2 months. Inevitably, the diseases, the exhaustion, the brutal discipline, and the suicides and rebellions provoked a very high mortality rate. For those who survived, though, the arrival in the New World was just the beginning of another traumatic and violent ordeal. If they were not branded and immediately dispatched to their new owners, slaves were cleaned up to mask their wounds and were placed on the auction block of a slave market; there, they were sold to the highest bidder, who would inevitably take them to a life of toiling in the fields or in the house of a plantation or farm (Rediker, 2008).

Slavery, Exploitation, and Control from Antiquity to the Modern Period

Even though, throughout history, there have been many societies that have utilized slavery as a violent and profitable system of oppression and exploitation, the importance of utilizing enslaved labor for the functioning of those societies has changed according to time and place. Following the definition first devised by Moses Finley, and then also by Keith Hopkins, most systems utilizing slavery in the course of history can be described as 'societies with slaves' in which slavery was present, but was not essential to the economic, social, and political structure. Conversely, only a few systems that utilized slavery can be considered 'slave societies,' in which slavery was at the heart of the economic, social, and political structure, and slaveholders and those who aspired to be slaveholders were the majority. For Finley and for a number of other scholars, only Classical Athens, Republican and Imperial Rome, the Early Modern and Modern Caribbean, the American South, and Brazil could be classified as authentic 'slave societies' (Burnard and Heuman, 2011).

In the classical world, slaves were ubiquitous and could be found performing all types of tasks in every dimension of the economy and society. Most of them tended to be household slaves, as in all premodern societies, but a large number of them were employed in back-breaking labor in agriculture. In either case, both in classical Athens and in Republican and Imperial Rome, slaves were subject to indiscriminate violence, and they were essentially at the whim of their masters, as they had little or no legal protection. Similarly to subsequent slave codes, particularly Roman law considered slaves as property, and violent punishment, torture, and murder of slaves by slaveholders were fairly common occurrences. In terms of treatment, though, Rome's household slaves fared probably better than others, especially if they were educated, since they could be given administrative tasks – which allowed them a higher quality of life than that of most slaves. The opposite was true of the slaves employed in the large farms and *latifundia*, and, even worse, in the mines. Similarly to slaves employed in other economically profitable businesses at later times, Roman agricultural slaves, who were essential to the functioning of the Roman economy, were chained, kept in barracks, and forced to hard labor from dawn to dusk under the constant supervision of overseers, who were in charge of their discipline and punishment (McKeown, 2011).

Both in medieval Europe and in the Islamic world, the substantial distinction between domestic and agricultural slavery persisted long after the fall of Rome, and the two types of forced labor maintained similar characteristics to the ones they had in Roman times, even though agricultural slavery was no longer an essential part of a large and integrated slave-based economic system. However, in northern Europe, by the later Middle Ages, serfdom replaced slavery in most agricultural regions, and consequently the legal conditions of agricultural laborers improved also in terms of protection from arbitrary violence and abuse. Conversely, slavery continued longer in the Mediterranean regions, and slaves coming both from eastern Europe and Africa were commonly employed under harsh, violently exploitative, labor conditions in agricultural labor in Palestine's Crusader states, in the Mediterranean islands, and in Spain and Portugal (Phillips, 1985). By the mid-1400s, when the Iberian kingdoms launched into the conquest of the Atlantic islands, and then of the New World, a tradition of violent exploitation of mass slave labor associated with profitable agricultural production, especially of sugar, was well established among southern Europeans and was exported by them into the Spanish Caribbean and Portuguese Brazil. Eventually, other European powers – notably the Dutch, then the French, and the British – also implemented plantation slavery, relying on the increasingly larger labor force violently uprooted from Africa through the transatlantic slave trade, and eventually succeeding one another as the dominant Atlantic slave economies in the Early Modern Period (Blackburn, 1997).

In the final decades of the eighteenth century, the end of colonial rule in North America's British Atlantic possessions, in Portuguese Brazil, and above all in French St. Domingue led to the making of the 'second slavery' (the type of capitalist oriented and highly exploitative slave system that characterized the nineteenth-century United States, Cuba, and Brazil) in the Americas – a slave system that was not necessarily tied to the logics of imperial expansion, but rather to the logics of capitalist profit in the world economy. Specifically in the US South, Cuba, and Brazil, the nineteenth century witnessed the growing and consolidation of the 'second slavery' through the mass organization of slave labor for the production of cotton, sugar, and coffee – the three New World agricultural products that dominated the world market. With the advent of the 'second slavery,' the type of violence that was intrinsic to the very texture of slavery became an indispensable component of a system of labor regimentation whose strict organization, enforced through constant supervision and a variety of disciplinary punishment, guaranteed the masters' extraction of the maximum amount of work from the slaves (Tomich, 2003).

Thus, in this sense, the 'second slavery' represented both the ultimate transformation and also the peak of an evolution of exploitative New World slave systems geared toward the maximization of production of particular agricultural items for sale and profit on the world market. Under the 'second slavery,' in response to the constant rise in market demand, pressure was placed on slaves on a continuously increasing basis in terms of regimentation and pace of work, both of which were enforced through the constant, efficient, and brutal use of violence, in order to guarantee fast and efficient mass production of particularly valuable cash crops. This was especially the case with the exhausting 'gang system,' according to which slaves worked divided in gangs, alternating each other in the different tasks required by the agricultural production in a never-ending routine of work operations that lasted uninterruptedly from dawn to dusk. Together with the consequences of the high level of violence implemented by masters, overseers, and slave drivers, this mindless routine resulted for the slaves, inevitably, in a phenomenon of workers' alienation comparable, with all the obvious differences, to the one that later on characterized twentieth-century factories (Dal Lago, 2012).

Resistance, Rebellion, and Revolution

In all the slave systems that existed in human history, slaves devised a variety of ways to resist the violent oppression brought upon them by slaveholders. Many of these forms of resistance were based on individual actions and were also nonviolent. Regarding slaves working in the fields, depending on the circumstances of the agricultural production and on the nature of supervision, resistance typically manifested itself through slowing or halting the pace of work, feigning illness, and, most dramatically, running away. The latter could sometimes take the form of mass flight, if the circumstances allowed it, as in the case of the thousands of Athenian slaves who fled during the Peloponnesian War (431–404 BC), or as in the case of the hundreds of thousands of runaway slaves in the Confederate South during the American Civil War (1861–65) (Burnard and Heuman, 2011).

In the Americas, especially during the Early Modern Period, mass flight of slaves led to the establishment of long-living 'maroon' communities, sometimes hosting thousands of runaway slaves. The largest of these communities was Palmares, in the captaincy of Pernambuco, in northeastern Brazil. Lasting from the early years of the seventeenth century to 1694, Palmares had a population of 11 000 runaway slaves, and it functioned as an independent kingdom, whose inhabitants fought fiercely in the wars brought upon them by both Portuguese and Dutch authorities in order to defeat them and re-enslave them. Especially in the eighteenth century, similarly to Palmares, even not on the same scale, large 'maroon' communities flourished also in other areas of the Americas, such as the interior of Suriname, eastern Cuba, and inland Jamaica. In all these cases, the existence of independent communities of runaway slaves prompted a reaction resulting in repeated violent attempts to suppress them, also because 'maroons' were instrumental in leading the other slaves into open rebellion against slaveholders. In Jamaica, in particular, the attempts at violent suppression of 'maroon' communities led to two prolonged conflicts: the First Maroon War (1665–1740) and the Second Maroon War (1795–96) (Blackburn, 2011).

The most straightforwardly violent form of slave resistance was outright rebellion. Throughout its history, slavery witnessed numerous examples of slave rebellions of different sizes and with different scopes. The rationale behind them was always the acquisition of freedom through violent means, but sometimes slaves could have a wider scope of overthrowing the entire slave system in an entire region as a first step toward ending slavery itself everywhere. Also, in general, aside from the only successful case of St. Domingue, all violent slave rebellions had negative results in both the short term, with the subsequent violent suppression of the rebels, and also the long term, with the increasing of violence in measures of oppression geared toward preventing the further occurrence of rebellions. The largest economic power founded on slave agricultural labor in the premodern world, ancient Rome, was shaken at the very core of its foundation by three large slave revolts occurring within the space of 100 years in the last two centuries of the Republican period and involving tens of thousands of slaves: the First Sicilian Slave War (137–132 BC), the Second Sicilian Slave War (104–100 BC), and the Spartacus Revolt (73–71 BC). All were violently suppressed by the Roman army with thousands of dead (Bradley, 1989).

In medieval times, an equally large slave revolt involved thousands of enslaved Zanj Africans, who rebelled against their Arab masters in the Abbasid Caliphate in AD 869–883. In the Americas, violent slave revolts occurred almost from the very beginning of the establishment of slave societies and continued throughout the Early Modern and Modern periods until slavery's final abolition. Many of these revolts actually remained at the level of large conspiracies, never materializing into action; many others, though, involved large numbers, from tens, to hundreds, to several thousand slaves. The following were among the most important large-scale slave rebellions in the Americas: Tackey's revolt (1760) and the Baptist War

(1831–32) in Jamaica; the Bahia slave revolts (1807–35) and the Male rebellion (1835) in Brazil; the Aponte (1812) and La Escalera (1843–44) rebellions in Cuba; and the Stono rebellion (1739), Gabriel's rebellion (1800), the German Coast uprising (1811), the Denmark Vesey conspiracy (1822), and the Nat Turner rebellion (1831) in the American South. Ultimately, regardless of the odds against them and the almost inevitable failures they were likely to face, through their violent rebellions, slaves demonstrated – in Gad Heuman's words – "that the enslaved were often prepared to resist their enslavement violently" (Heuman, 2011: 231).

By far, the most important example of violent slave rebellion in world history is the Haitian Revolution in St. Domingue, which occurred at the end of the eighteenth century and effectively decreed the end of the colonial slave system in the New World. In the second half of the eighteenth century, the French colony of St. Domingue was the leading producer of sugar, which was grown in large plantations with hundreds of slaves owned by a small elite of white planters and mulattoes, both resentful of their dependence on France; at this time, also a respectable minority of free blacks was present in the island. The revolutionary events that started in France in 1789 provided the white elite of St. Domingue with the opportunity to seek autonomy from the French metropole through the drafting of a constitution, in 1790, that limited French control. Yet, in 1791, taking advantage of their much superior numbers, St. Domingue's slaves organized a series of revolts that, by 1792, encompassed the entire Haitian territory; as a consequence, most of Haiti's white population was slaughtered in the process. By 1793, self-liberated 'black Jacobin' Toussaint L'Ouverture, acknowledged leader of the Haitian Revolution, was able to proclaim the end of slavery, and then, in 1794, the independence of Haiti – the same year the Jacobin Convention in Paris decreed the end of slavery in all the French colonies (Blackburn, 2011). Even though, later on, the rise of Napoleon in France led to the restoration of slavery in the French Empire and to repeated attempts to establish control on St. Domingue, the newly born Haitian Republic succeeded in maintaining its independence, and thus also its ban on slavery, and was officially recognized as a sovereign state in 1804. Effectively, Haiti's recognition as a nation marked not just the end of the colonial slave system in the Americas, but also, more importantly, the positive outcome of the only successful violent slave revolt in world history; in this sense, therefore, the Haitian Revolution is an exception that has given much food for thought to scholars of slavery (Genovese, 1979).

Peaceful versus Violent Abolitionism

(Abolitionism is the collective term for movements aiming at the abolition of either slavery or the slave trade.) Concerted efforts at opposing slavery and bringing about its abolition are a wholly modern feature in human history. In the past 50 years, scholars have determined through a number of studies that, in the later decades of the eighteenth century, for the first time in history, a combination of factors led to the beginning of attacks on the institution of slavery geared toward influencing the public opinion and with slavery's abolition as their ultimate objective. Among these factors, particularly important were the influence of Enlightenment doctrines of human rights, the rise of the classical political economic theory of capitalism, the increasing religious emphasis of Evangelical confessions on the sin of slavery and the leverage of powerful antislavery Christian groups such as the Quakers, and, above all, the emergence of influential white and black radical antislavery spokesmen and organizations. As a consequence of these momentous developments, nonviolent antislavery associations began to be increasingly vocal especially in the English-speaking world, eventually coalescing in England around a movement for the abolition of the British slave trade, headed by William Wilberforce and Thomas Clarkson. As a result of this crucial nonviolent antislavery activity, the Atlantic slave trade was abolished in the British Empire in 1807; significantly, the following year, also the United States abolished its own slave trade (Blackburn, 2011).

Beginning in the late 1820s, nonviolent antislavery forces in the English-speaking world began to pursue a radical agenda focusing on the achievement of immediate abolition of slavery. In Britain, the Anti-Slavery Society's Agency Committee, headed by Thomas Fowell Buxton, engaged in a massive effort in order to disseminate abolitionist literature and petitions to be signed and presented in Parliament. The result of this effort, together with the fear of constant slave rebellions, and changing economic logics, led the British Parliament to pass the 1833 Emancipation Act, which freed all the slaves in the British Empire. (Emancipation is the official abolition of slavery decreed by a government's act; Manumission is the master's voluntary act of freeing his/her own slaves.) In the following decade, partly stimulated by developments in Britain, the French Republican Government also abolished slavery peacefully throughout the French Empire by 1848. In the United States, similarly to what happened in Britain, a nonviolent abolitionist movement, in this case supported by both black and white activists, had begun its activities in the early 1830s, with William Lloyd Garrison's publication of *The Liberator* and with the 1833 foundation of the American Anti-Slavery Society. Unlike their British counterparts, though, American abolitionists were not successful in the short term, and their plans for persuading the majority of the public opinion to support immediate emancipation did not lead to any concrete result (Davis, 1984).

Even though the American abolitionist movement had always been challenged by some individuals who advocated more violent approaches to the problem of immediate emancipation of the slaves, it was the increasing confrontational nature of the issue of slavery's expansion in the western territories of the United States, in the 1840s that led to the rise in violent abolitionist actions against the southern slave system organized by militant abolitionists, who did not believe any longer in pressurizing the public opinion. Thus, during the 1850s, the decade that preceded the occurrence of the American Civil War, radical antislavery activists such as James Redpath and John Brown openly advocated a mass slave insurrection as the only viable means to bring about a violent end to slavery in the US South. Most famously, in 1859, John Brown embarked in his raid on Harper's Ferry with the intention of seizing an arsenal and provoking a massive slave revolt, and thus precisely with this objective in mind (Davis, 1984).

Peaceful versus Violent Endings of Modern Slavery

In the second half of the nineteenth century, the process leading to emancipation in the United States, which was a direct result of the American Civil War, stood in stark contrast with the end of slavery in both Cuba and Brazil, which occurred in a relatively peaceful manner, more similar to the processes that had led to the 1833 end of slavery in the British Empire and to the 1848 end of slavery in the French Empire. In the second half of the nineteenth century, Cuba was still a colony of the Spanish Empire. In the course of the 1860s, the rise of the first Spanish abolitionist society in 1864, and then the Spanish Government's abolition of the Atlantic slave trade in 1867, did a great deal to erode the Cuban planters' power. Subsequently, the creation of the first Spanish Republic in 1868, and the consequent rise of a movement for Cuban independence by the planters in the eastern part of the island during the Ten Years' War (1868–78) precipitated events. In 1870, in order to curb the planters' separatist effort, the Spanish Government issued the *Moret Law*, according to which both the children born of slave mothers since September 1868 and the slaves who were 60 years old or older were free. Then, the subsequent 1880 *Patronato Law* effectively decreed the end of slavery in Cuba starting from 1886 (Drescher, 2009).

In comparison with Cuba, in Brazil, British pressures on the Brazilian Government had led already to a major change in policy, with the abolition of Brazil's Atlantic slave trade in 1850. Then, Brazil's imperial government issued the 1871 *Rio Branco Law*, which freed the children born of slave mothers. Particularly crucial for further developments were, in the following decade, Joaquim Nabuco's 1880 foundation of the *Sociedade Brasileira Contra a Escravidão* (Brazilian Anti-Slavery Society), together with international pressure, and also the initiative of provinces such as Ceara, which abolished slavery in 1884. In 1885, the imperial government passed the *Dantas-Saraiva-Cotegipe Law*, which freed slaves who were 65 years of age, while increasingly larger numbers of runaway slaves fled plantations and farms, and finally, 3 years later, the imperial government decided to proclaim the end of slavery throughout the country with the *Golden Law* of 1888, which decreed slaves immediately and permanently free. Effectively, the 1888 *Golden Law* was one of only two official governmental acts – together with the 1863 US *Emancipation Proclamation* – that freed the slaves unconditionally and without compensation for slaveholders, unlike the case in all the other slave societies (Blackburn, 2011).

In the United States, slavery – particularly its expansion in the western territories – was, effectively, the main issue in national politics since the 1840s. In 1854, the antislavery forces formed the Republican Party specifically with the objective of preventing the expansion of slavery, and 6 years later Republican candidate Abraham Lincoln won the 1860 presidential election with the majority of the northern votes. Soon after, 11 slaveholding states seceded from the Union and formed the Confederacy, a nation wholly committed to the preservation of slavery, plunging the country into a 4-year-long Civil War (1861–65), which would cost more than 600 000 dead – effectively, the cost in human lives of the southerners' violent resistance to the US Government's enforcement of emancipation (Davis, 2006).

While, initially, Lincoln did not fight the war with the intention of freeing the slaves, a combination of factors – chief among them the protracted length of the war, the actions of the slaves, who fled in mass to Union camps, and the increasing importance of Radical Republicans and Abolitionists in Congress – led gradually to his conviction of the necessity of enacting emancipation. In September 1862, after a major Union victory at Antietam, Lincoln drafted the *Preliminary Emancipation Proclamation*, whose definitive version became the 1 January 1863 *Emancipation Proclamation*. Justified by Lincoln as a war measure, the 1863 *Proclamation* declared immediately and forever freed all the slaves in areas under Confederate control, gave legal backing to the slaves' efforts to free themselves, and gave the Union Army the legal power to help them with military action in their efforts of self-liberation. Soon after, African-American soldiers enlisted in the Union Army, and their number rose to reach almost 200 000 units at war's end. Then, in 1865, Congress passed the *Thirteenth Amendment* to the Constitution, officially abolishing slavery throughout the United States. Thus, unlike emancipation in Cuba and Brazil, and unlike the majority of the processes of emancipation in slave societies in world history – with the notable exception of Haiti – US Slave Emancipation was possible exclusively as a direct consequence of the victory of the Union in a major war fought by antislavery forces against a particularly powerful class of slaveholders, who violently resisted slavery's abolition, with a consequent large loss in human lives (Davis, 2006).

The Resurgence of Violent Slavery in the Twentieth Century

In the twentieth century, violent practices of exploitation employing slave labor reared their head again, largely as a direct consequence of the rise of totalitarian regimes, which plagued the recent history of a number of different countries from Europe to Asia. In all these regimes, a crucial common feature was the creation of systems of labor camps, where captives, prisoners of war, opponents, and dissenters were forcibly enclosed and forced to submit to exhausting labor schedules under strict supervision and the threat of violent punishment – essentially in conditions that replicated, albeit in modern settings and within the context of production efforts often related to the modern needs of technological warfare, the common life of enslaved laborers in the large slave systems of the Atlantic before the abolition of slavery. It is important, therefore, to end this succinct analysis of the historical relationship between slavery and violence by briefly looking at the best-known example of resurgence of violent slavery and employment of slave labor in twentieth-century Europe: the Nazi concentration camps (Davis, 1984).

Concentration camps with the employment of mass forced labor had been present in both the German Empire and the Austro-Hungarian Empire during World War I, and they were set up in Germany already from the very beginning of Hitler's rise to power in 1933. However, with the large-scale expansion of the Third Reich during World War II, the mass employment of forced labor by the Nazi Government became a necessity, as between 1939 and 1945, 13 million Germans were employed in Hitler's army and needed to be replaced and also supported

in the war effort by at least an equal number of forced laborers. Thus, as Nazi power expanded, especially in eastern Europe, millions of civilians and prisoners of war were enslaved and sent to toil in forced labor, either in concentration camps, under the supervision of SS units, or in agricultural fields, or in armament factories. At the heart of this massive effort were the two ideological concepts of *Lebensraum* (living space), which was a large area at the core of the projected Reich, to be conquered by the army and settled by Germans, and of the *Untermenschen* (inferior races), which were the racially defective people that pure Aryans, i.e., Germans, would enslave and force to labor in the conquered territories until they ceased to be useful and would be disposed of in order for them to not threaten German racial purity (Drescher, 2009).

Yet, while the violence of enslavement and the exploitative conditions of forced labor, with the exhausting pace and the threat of discipline and punishment, often resulting in death, were features that make Nazi concentration camps comparable to slave plantations in the New World, the actual value placed upon slave labor was very different in the two situations. For one thing, Nazi slaves were not bought or sold on slave markets, and therefore they were not in themselves a source of capital as slaves in New World plantations. More importantly, Nazi obsession with racial purity effectively prevailed over the pressing economic needs for enslaved labor. In the end, with the Holocaust, as Seymour Drescher has remarked, Nazi Germany, "a state with a greater appetite for forced labour than all previous colonial systems in the Americas combined, destroyed far more potential workers in four years than were lost in the Atlantic transit of Africans in the course of four centuries" (Drescher, 2009: 438).

Conclusion

While violence in general has characterized the history of slavery from its inception, specific modes of violence have characterized the different stages of the experience of slavery for the enslaved according to different times and places. The process of enslavement itself resulted from the violence of uprootedness associated with the practices of warfare conducted for the purpose of conquest or else kidnapping, and then the equally traumatic processes of sale and purchase in the slave markets. Equally violent and traumatic were the actual experiences of laboring under slavery, with its inevitable accompaniment of strict discipline and punishment, especially in those cases in which slave agricultural production was geared toward the maximization of the slaveholders' profit. Violence also characterized a great deal of the slaves' response to their own violent oppression and exploitation, through the staging of slave rebellions of different sizes and with different scopes throughout history. Ultimately, though, in the large majority of the cases, aside from the notable exceptions of the Haitian Revolution and the American Civil War – and leaving aside the twentieth-century slave regimes – the end of slavery came relatively peacefully and as a result of governmental decrees that eased the nonviolent transition from slave to free labor, even though almost always not bringing an end to the ex-slaves' economic exploitation.

Abstract

Slavery has been a permanent part of the human condition throughout history, though not present in all cultures or societies all the time. This article examines contemporary forms of slavery, recognizing that an estimated 29.8 million persons are enslaved in the world today. This article examines four aspects of contemporary slavery: its definition; estimation of its prevalence; risk factors that support or predict enslavement; and policy measures taken to mitigate its spread.

Slavery has been a permanent part of the human condition throughout history, though not present in all cultures or societies all the time. Though sometimes referred to as an 'institution,' it is not one in the precise meaning of that term, which is used to describe those key organized activities that are and have been present, in one form or another, in all societies and cultures, such as economic exchange, processes of socialization, religious expression, or some form of family organization. Put simply, slavery is common throughout history and in evidence in most countries today, but it is not a universal attribute of societies. Put another way, it cannot be assumed to be an innate characteristic or attribute of human beings.

This article examines contemporary forms of slavery, recognizing that, according to The Global Slavery Index (2013), an estimated 29.8 million persons are enslaved in the world today. This article examines four aspects of contemporary slavery: its definition; estimation of its prevalence; risk factors that support or predict enslavement; and policy measures taken to mitigate its spread.

Defining Slavery

Slavery has existed since the dawn of civilization. Aristotle (2013[350 BCE]) wrote: "The slave is a part of the master in the sense of being a living but separate part of his body." Aristotle's comment illustrates how, at its most basic level, slavery is a relationship between two individuals – the enslaved and the slaveholder, characterized by an asymmetrical power differential in which the slaveholder has complete control over the enslaved. The nature of this control ultimately depends on social, psychological, economic, geopolitical, and cultural factors. The method of this control most often includes an interaction of physical, emotional, and sexual violence. For nearly all enslaved females (and some males), this control means being raped by the slaveholder. This often generates trauma and posttraumatic stress within the enslaved. Indeed, the least studied but crucial attributes of slavery are its physical and psychological sequelae.

Although slavery has existed for thousands of years, contemporary slavery is different from the past in at least two ways. First, the cost of a slave today is very low. In Moldova, for instance, through an illicit transaction, a slave can be purchased today for about $200 USD, and in Haiti for about $50 USD (Skinner, 2009). Two hundred years ago, by contrast, in the American South, the cost of a slave was about $1000 USD, which, adjusted for inflation, is about $45 000 USD today (Bales, 2012). Compared to the past, when slaves tended to be capital investments, their acquisition cost is now so low that they might be thought of as disposable inputs to economic enterprises. For example, it can be more cost-effective for slaveholders to simply replace ill or injured slaves rather than pay for their treatment.

A second way in which contemporary slavery is different from the past is that slavery today is universally illegal. This contrasts with most of human history in which slavery was a legally sanctioned, socially acceptable practice. For example, slavery is mentioned throughout the Old and New Testaments and is simply accepted everywhere in the Bible as a customary social arrangement. The result is that compared to its historically legal form, slavery today has become a hidden criminal activity, supported by governmental corruption and global competition to profit from the lowest marginal costs.

Arriving at an operational, legal, or conceptual definition of contemporary slavery is a challenge, given the substantial disagreement among scholars, policy makers, international organizations, activists, and other stakeholders. Today there are many definitions of slavery; one of the most inclusive is the 2012 Bellagio-Harvard Guidelines on the Legal Parameters of Slavery. These guidelines build upon the 1926 Slavery Convention of the League of Nations, which defines slavery as "the status or condition of a person over whom any or all of the powers attaining to the right of ownership are exercised." The Bellagio-Harvard Guidelines specify that the exercise of "the powers of the right of ownership" "should be understood as constituting control over a person in such a way as to significantly deprive that person of his or her individual liberty. Normally this exercise is supported by and obtained through means such as violent force, deception and/or coercion, with the intent of exploitation through the use, management, profit, transfer or disposal of that person." These guidelines conceptualize slavery as an umbrella term under which the various types of enslavement can be understood.

The practice of slavery has always been based upon rationalizations and justifications on the part of slaveholders. In the past, racist ideas of superiority/inferiority provided one justification for enslaving certain populations. Race, however, is just one of many rationalizations utilized to support slavery

in the past and today, others include religion, ethnicity, and gender. Indeed, any form of social discrimination, at its most extreme, might be taken to two ultimate outcomes: enslavement and/or murder (including genocide).

Perhaps the most widespread form of slavery today is debt bondage (also referred to as bonded labor), in which the rationale for enslavement is an obligation linked to a debt. While some legal instruments and commentators falsely assume that the slavery exists because a debt can never be repaid due to the low wage being earned and the high interest rate being charged, this is incorrect. The foundation of slavery is the violent physical and psychological control exerted by the slaveholder, and once the slave has been obtained through the justifying mechanism of debt (or race or religion or some other mechanism), it is the violent force, fraud, and coercion that maintains the enslavement. Forms of debt bondage have existed for thousands of years and continue to this day. It is substantial in South Asia, particularly within India's long-standing caste system, in which the lowest caste (Dalits) and other 'Scheduled Tribes' are enslaved in agriculture, brick kilns, mills, and factories, sometimes for generations. The plight of those caught in this hereditary form of collateral debt bondage slavery reminds us that forms of slavery cannot always be easily separated into 'new' and 'old' forms. Families in South Asia, sometimes entire villages, are found to be enslaved for many generations, and living without knowledge of their rights or the possibility of freedom.

Another common type of slavery is contract slavery, in which a slaveholder procures apparently legal documentation for a person to work, but once employed, that person is enslaved. False contracts mislead unsuspecting victims to believe that their work is legitimate (Bales, 2012). Examples of contract slavery include: South Asian women offered jobs as waitresses in Japan and offered the requisite legal travel documentation, but who, upon arrival in Japan, are forced into prostitution (Bales, 2008); Mexican immigrants in the United States offered jobs as day laborers picking tomatoes in Florida, but who, upon arrival at a tomato farm, are not allowed to leave of their own free will; and Nepalese migrants offered jobs as construction workers in Qatar, but who then are forced to work without pay and left begging for food. It should be noted that contract slavery is often linked to debt bondage slavery when a worker borrows money from the slaveholder or other brokers. A common scenario is borrowing to cover transportation costs to go from the home country to a destination country, and finding that debt dramatically increased and used as a rationale for enslavement.

Perhaps the most underreported and least studied form of contemporary slavery is forced marriage, in which either one or both parties have not agreed to the act and violence or threats are used to force a person into the 'marriage.' In most instances, the victim is female. Politically, a challenge arises in responding to forced marriage, given that some argue that this practice is sanctioned by cultural norms and parallel legal systems such as tribal, customary, or religious laws, and therefore outside the purview of existing legal prosecution and adjudication.

Another less publicized form of slavery, as defined by one UN Convention as human trafficking, is organ trafficking. This falls under three broad categories: first, when a trafficker forces a victim to give up an organ; second, when a victim contractually agrees to sell an organ but is not paid; and third, when a victim is being treated for an ailment and, unbeknownst to them, an organ is removed (United Nations, 2014). The illegal trade of kidneys, for instance, has risen to the extent that the World Health Organization estimates one kidney is sold every hour on the illicit market (Campbell and Davison, 2012).

Despite the variety in the types of contemporary slavery, the most publicized form in developed nations is sex trafficking, due to its prominence in popular culture, policy circles, and the media. One prominent definition of sex trafficking in the United States comes from its federal Trafficking Victims Protection Act, which defines it as "the recruitment, harboring, transportation, provision, or obtaining of a person for the purpose of a commercial sex act where such an act is induced by force, fraud, or coercion, or in which the person induced to perform such act has not attained 18 years of age" (U.S. Congress, 2000). It should be noted that, on the demand side of sex trafficking, purchasers of commercial sex come from all social strata, including the educated, uneducated, wealthy, poor, rich, and famous. To this extent, mainstream society economically supports the global sex trade. This has generated a conversation particularly within the United States faith-based community about abolishing prostitution as a viable way to end sex trafficking.

Forced commercial sexual exploitation is only one way that slavery interacts with mainstream society. Scholars have documented many instances of the enslaved used in the production of commodities that flow into the global supply chain (Bales and Soodalter, 2009). Originating from numerous countries, slave labor is found in the production of textiles, gemstones, apparel, and agricultural products like cocoa, coffee, and sugar. In the Congo, for instance, armed gangs force the enslaved to dig for minerals such as coltan, cassiterite, wolframite, and tungsten used in the production of cell phones, laptops, and other electronic devices. Slavery is therefore a significant, albeit small, factor in global economic output. At the same time, because many Fortune 500 companies invest in or purchase from subsidiary companies that employ a modicum of slave labor in their product supply chain, it can be assumed that a number of mutual funds also have a small percentage of slave labor in their portfolios. At the aggregate, one estimate suggests that about $44 billion USD per year is made in slavery-derived profits (Belser, 2005).

Estimating the Prevalence of Slavery

Estimating the number of enslaved in the world today is a challenge given its hidden, illicit nature. Slaveholders naturally restrict freedom of movement of the enslaved, such that it is difficult for the enslaved to signal their location and situation to a third party. Moreover, with the possible exception of sex trafficking, many forms of contemporary slavery do not leave a lasting impression on the public eye. This includes domestic workers who appear willingly employed but are held under threat of violence and agricultural workers trapped on farms away from public view. It also includes low-skilled workers in remote villages in developing countries with little access to help.

Scholars are just beginning to apply social science research methods to account for the hidden nature of slavery. One method, although not widely available, is to obtain representative sample survey data of the general public, with the aim of eliciting the true level of slavery across the population. Some antislavery organizations and scholars are pioneering this technique, but the challenge is to elicit unbiased responses from respondents who are asked to comment on a crime (slavery), about which they may feel uncomfortable speaking candidly. Moreover, the implementation of such representative sample surveys on a large scale can be financially prohibitive, thus delaying the commission of such surveys on a widespread systematic basis. Another, more widely applied method has been for separate survey research teams to go into the field and collect separate counts of the enslaved in regions where there is a high probability of enslavement. From these lists, researchers then calculate an estimate of the population proportion enslaved. Yet another method is to mine the relatively large literature on primary and secondary source materials from governments, nongovernmental organizations, and journalistic accounts that have chronicled contemporary slavery. Based on these primary and secondary sources, scholars can also estimate the proportion of the population enslaved, although with a high degree of uncertainty. Still other approaches employ several of these techniques at the same time, to varying degrees of accuracy and success.

A problem common to all of these methodologies, however, is that, because operational definitions of slavery differ across scholars, governments, activists, and other stakeholders, some methods may deliberately or inadvertently exclude some major types of slavery. Forced marriage, for example, is often not counted in most studies of contemporary slavery's prevalence, although some scholars estimate the number of people in forced marriages may be in the millions. This suggests that most estimates of modern day slavery are likely underestimates. As to the extent to which these underestimates differ from the true proportion of the population enslaved remains unknown. Further complicating this methodological challenge is the norm that, at least until very recently, most survey researchers based in NGOs and IGOs have not shared their methods or results in a transparent fashion from which to build a common database.

Several oft-quoted estimates of slavery's global prevalence do exist however; the most common estimate is 27 million slaves. The author of that study, however, relying upon more precise representative sample survey data, recently updated that sum to 29.8 million (Bales et al., 2013). Other studies suggest the prevalence of slavery is closer to 21 million (ILO, 2014). Most likely, the divergence in these counts (21 million vs 29.8 million slaves) is best explained by differences in the operational definition of slavery and the methodology used to estimate the prevalence of the enslaved.

Like the estimation of slavery at the global level of analysis, differences also exist in estimating slavery at the level of the nation-state. The United States is illustrative. One study estimated that at any given time there are 10 000 or more people enslaved in the United States (Free the Slaves, 2005). Another study suggested there are upward of 60 000 people enslaved – an increase by a factor of six (Bales et al., 2013). Such widespread deviation among these studies leaves little room for policy makers to have a firm grasp of what the real prevalence of contemporary slavery might be. Similar variation in the estimated enslaved exists for other nations, such as the United Kingdom. In the meantime, some studies of prevalence are being conducted in West Africa, but are only at the early stages. Most likely, there will also be significant variation in what these estimates yield as well.

A substantial lacuna therefore exists on ways to measure reliably the prevalence of contemporary slavery, at both the level of the nation-state and the global level of analysis. This concern has been underscored by the US National Institute of Justice (NIJ), which conducted a comprehensive review of the antitrafficking literature in 2008 and found, "quantitative methodologies are noticeably scarce" and that, "the dominant anti-trafficking discourse is not evidence based" (Goździak and Bump, 2008). Moreover, the NIJ review found that only 16% of the 218 academic articles on contemporary slavery were both peer reviewed and based on empirical research. This means that the majority of scholarship on contemporary slavery has not been subjected to routine standards of social scientific inquiry, such as evaluating a given hypothesis in light of one or more competing explanations.

A more methodologically robust inquiry into the prevalence of contemporary slavery is needed to shed more light on this hidden crime. Although representative random sampling would be ideal for additional studies, particularly at the global level, its prohibitive cost makes this approach challenging, if not untenable, especially for scholars in the developing world who do not have financial access to large survey polling organizations. A potentially innovative approach, methodological approach, is multiple systems estimation (MSE). The MSE methodology originated in the biological sciences, and has been applied in recent years to problems in epidemiology and estimating civilian casualties in war zones. As Manrique-Vallier et al. explain, "MSE methods attempt to estimate the number of cases that were not included in lists that partially enumerate a closed population." Through generating different lists of potential victims of human trafficking (gathered from social services, law enforcement, immigration officials, etc.), scholars can use MSE statistical modeling techniques to identify the hidden population of the enslaved.

Another way to generate better prevalence estimates of contemporary slavery involves more substantial cooperation among key stakeholders. As Goździak and Bump (2008) recommend: "There is a need to establish a forum where research results can be exchanged between different scholars as well as shared with policy makers and service providers; such a forum can take a form of a specialized publication or an international task force." This is a matter of political will and organizational capacity.

The Risk Factors That Help Explain Why People Are Enslaved Today

In this section, we explore how the amount of modern slavery in a country is related to other important factors such as corruption and human development. It is important to uncover these relationships since they can help determine effective efforts for ending modern slavery. Note that global trends and

Figure 1 A correlation plot between slavery prevalence and corruption in 2013. Source: Global Slavery Index: http://www.globalslaveryindex.org.

relationships are generalized findings, and do not represent the unique situation of any one country. What is important is that these measurements of co-relationships point to patterns of risk, vulnerability, and interaction in the dynamic crime of modern slavery. Risk itself is measured along five dimensions: the antislavery policies (or lack thereof) of the country where a person lives; the level of human rights afforded to a person in the country in which they live; the level of economic and social development of a country; the stability of the state and law enforcement of the country in which a person lives; and the levels of discrimination a person faces (Bales et al., 2013). Different components of these dimensions can be compared statistically with prevalence levels of slavery across countries.

These statistical correlations tell us two things: first, whether there really is a relationship between the occurrence of modern slavery and another factor; and second, the strength of that relationship. The research literature notes ample examples of corruption being implicated in modern slavery. This is no surprise; if the rule of law is effective, it protects citizens from being enslaved. If the rule of law is corrupted, people are not protected and criminals can pay off officials and act with impunity.

Figure 1 examines the relationship between corruption (as measured by Transparency International) and the prevalence of modern slavery (as measured by the Global Slavery Index) for 162 countries. Note that the data from the Global Slavery Index correspond to the *y*-axis in Figure 1, which ranges from a score of 1 (very low prevalence) to a score of 162 (very high prevalence). Note that the data from Transparency International correspond to the *x*-axis in Figure 1, which ranges from a score of 0 (high corruption) to a score of 100 (very low corruption). Each dot in Figure 1 represents a country. This graph illustrates a strong relationship between the prevalence of modern slavery and corruption ($R^2 = 0.61$), statistically significant at the 0.01 level.

The research literature also frequently draws connections between levels of human development, particularly poverty (including factors such as availability of health care, education, and levels of income) and modern slavery. Figure 2 examines the relationship between human development (as measured by the United Nations Development Programme Human Development Index (HDI) along the *x*-axis) and prevalence of modern slavery (as measured by the Global Slavery Index along the *y*-axis) for 162 countries. Note the upward sloping shape of the graph, which suggests higher levels of modern slavery correlate with lower levels of the HDI (and conversely, lower levels of modern slavery correspond to higher levels of HDI).

The level of a country's human development reflects its economic well-being, which in turn affects the poverty levels and deprivation a citizen might face. On the other hand, higher levels of educational attainment, elevated health care, and the chance of effective citizenship, all tend to allow people to protect themselves from vulnerability to modern slavery. This finding is statistically significant ($p > 0.01$) and the correlation score ($R^2 = 0.74$) points to a strong relationship between modern slavery and development.

A common pathway to slavery is through debt obligations. When access to legal sources of credit is not available, the poor and vulnerable will sometimes turn to other types of lending, even to the mortgaging of their own lives. Access to financial services can be crucial for upward social mobility, which brings the economic stability that helps to protect against enslavement. Figure 3 shows the relationship between access to financial services and the prevalence of slavery for 161 countries. This finding is statistically significant ($p > 0.01$) and the correlation score ($R^2 = 0.63$) suggests a strong relationship.

Current Policy Measures Taken to Mitigate the Spread of Slavery

There is a paradox concerning the policy and legal measures in place to end or mitigate the spread of slavery. Slavery is illegal in every country, it is forbidden by a number of international instruments, and it is one of a handful of human activities that

Figure 2 A correlation plot between slavery prevalence and the Human Development Index in 2013. Source: Global Slavery Index: http://www.globalslaveryindex.org.

Figure 3 A correlation plot between slavery prevalence and access to financial services in 2013. Source: Global Slavery Index: http://www.globalslaveryindex.org.

are of such severity and the popular consensus of approbation is so great that it is considered a *jus cogens* violation. This type of violation is subject to a fundamental and overriding principle of international law from which no derogation is permitted, also referred to as a 'peremptory norm.' This is a principle accepted by the international community of states that overrides or surmounts other laws. The prohibitions of genocide, maritime piracy, slavery and the slave trade, torture, and wars of aggression and territorial aggrandizement, are generally accepted as *jus cogens* norms. In other words, there is an absolute and global prohibition of slavery and all its related activities.

At the same time, and in the face of this absolute and global prohibition, slavery exists in every country, and policies, laws, and especially the resources needed to address this crime are poor or lacking. Two examples drawn from the United States, one of the most active of national governments in their anti-slavery policy, illustrates this mismatch between the size of the problem and the size of the response. According to one State Department estimate, there are approximately 17 000 new slaves in the United States each year – comparable to the average of around 17 000 homicides in the United States each year. Across all US law enforcement provision (local, state, and federal police/agents), there are about 45 000 trained homicide

specialists, but only about 200 trained antislavery specialists. This disparity in trained personnel results in national homicide clear-up rates of 70–75% and slavery/trafficking clear-up rates of less than 1%. This fundamental pattern is repeated globally across all countries and governments.

Expansion and training of enforcement personnel would be critical to success to mitigation and eradication. Yet, in terms of financial resources, in 2012, US federal expenditure on reducing the criminal activity of slavery and human trafficking is less than that devoted to military bands within the Department of Defense. For comparison, the estimated cost of global eradication of slavery, over a 25-year period, is $11 billion, which is one-half the yearly cost of the US government's War on Drugs. It is important to reiterate that the United States is one of the world's leading countries in addressing slavery and trafficking in policy, law, and resources.

It can be argued that Brazil is a world leader in terms of antislavery policies. There are three distinct provisions that Brazil has enacted that have been shown to be effective. First, in 2002, the government of Brazil initiated a national slavery eradication plan. This brought together all relevant agencies with law enforcement and appropriate nongovernmental organizations as well as unifying and resourcing the legal response. First-year (2003) results were 4789 slaves freed. Second, Brazilian experience also showed the value of specialist federal antislavery squads with attached labor inspection and enforcement personnel. Many, if not most, countries have specially trained antidrug units, but specialist antislavery units, though effective, are rare. Finally, Brazil also established a 'dirty list' of any people or companies that were found to use slave labor. The list is published on the Internet and regularly updated. Being on the list excludes companies from receiving any sort of government funds, grants, or credits. Since much of the process of opening and developing land relies on government tax credits or support, this effectively drives slave-using companies and individuals out of that business. Consumers can determine which companies they would wish to avoid in order to avoid slave-based products.

Slavery: Comparative Aspects

Orlando Patterson, Harvard University, Cambridge, MA, USA

Abstract

In the comparative study of slavery it is important to distinguish between slave holding societies and large-scale, or what Moses Finley called 'genuine,' slave societies. The former refers to any society in which slavery exists as a recognized institution, regardless of its structural significance. Genuine slave societies belong to that subset of slave holding societies in which important groups and social processes become heavily dependent on the institution.

The institution of slavery goes back to the dawn of human history. It remained important down to the late nineteenth century, and persisted as a significant mode of labor exploitation in some Islamic lands as late as the second half of the twentieth century. Remnants of it are still to be found in the twenty-first century in a few areas. Yet it was only in a minority of cases that it metastasized socially into genuine slave societies, though in far more than the five cases erroneously claimed by Keith Hopkins. Thus, the institution existed throughout the ancient Mediterranean, but only in Greece and Rome (and, possibly, Carthage) did genuine slave societies emerge. It was found in every advanced precapitalist society of Asia, but only in Korea did it develop into large-scale slavery. All Islamic societies had slavery, but in only a few did there emerge structural dependence on the institution. In all, there were approximately 50 cases of large-scale slavery in the precapitalist world. With the rise of the modern world, slavery became the basis of a brutally efficient variant of capitalism. There were at least 40 such cases, counting the Caribbean slave colonies as separate units.

This article examines two sets of problems. The first concerns those factors associated with the presence of institutionalized slaveholding. The critical question here is: why is the institution present in some societies yet not in other, apparently similar, ones? The second set of problems begins with the assumption that slavery exists, and attempts to account for the growth in significance of slavery. More specifically, such studies attempt to explain the origins, structure, dynamics, and consequences of genuine slave societies.

In the comparative study of slavery it is important to distinguish between slave holding societies and large scale, or what Moses Finley called 'genuine,' slave societies (Finley, 1968). The former refers to any society in which slavery exists as a recognized institution, regardless of its structural significance. Genuine slave societies belong to that subset of slave holding societies in which important groups and social processes become heavily dependent on the institution.

The institution of slavery goes back to the dawn of human history. It remained important down to the late nineteenth century, and persisted as a significant mode of labor exploitation in some Islamic lands as late as the second half of the twentieth century. Remnants of it are still to be found in the twenty-first century in a few areas. Yet it was only in a minority of cases that it metastasized socially into genuine slave societies, though in far more than the five cases erroneously claimed by Keith Hopkins (1978). Thus, the institution existed throughout the ancient Mediterranean, but only in Greece and Rome (and, possibly, Carthage) did genuine slave societies emerge. It was found in every advanced precapitalist society of Asia, but only in Korea did it develop into large-scale slavery. All Islamic societies had slavery, but in only a few did there emerge structural dependence on the institution. In all, there were approximately 50 cases of large-scale slavery in the precapitalist world. With the rise of the modern world, slavery became the basis of a brutally efficient variant of capitalism. There were at least 40 such cases, counting the Caribbean slave colonies as separate units (for the most complete list, see Patterson, 1982: App. C)

This article examines two sets of problems. The first concerns those factors associated with the presence of institutionalized slaveholding. The critical question here is: why is the institution present in some societies yet not in other, apparently similar, ones? The second set of problems begins with the assumption that slavery exists, and attempts to account for the growth in significance of slavery. More specifically, such studies attempt to explain the origins, structure, dynamics, and consequences of genuine slave societies.

Comparative Approaches to Slaveholding Societies

There is now a vast and growing body of literature on slavery (Patterson, 1977a; Miller, 1993; Miller and Holloran, 2000). Yet, with the notable exception of certain anthropological studies (to be considered shortly) relatively few recent works are truly comparative in that they aim to arrive at general conclusions about the incidence, nature, and dynamics of slavery. Even those few works that compare two slaveholding societies tend to be concerned more with highlighting, through contrast, the distinctive features of the societies under consideration. This highly particularistic trend marks a regrettable departure from earlier studies of slavery.

The evolutionists of the nineteenth century were the first to offer explanations for the presence of slaveholding. Their basic proposition – that there was a close relationship between stages of socioeconomic development and the rise of slavery – has received no support from modern comparative studies (Pryor, 1977). However, some of their less grandiose views have survived later scrutiny. One was their emphasis on warfare, and the demand for labor at certain crucial points in

their scales of development as the important factors (Biot, 1840; Westermarck, 1908). The other was their finding that the socioeconomic role of women was critical. It was claimed, for example, that the subjection of women provided both a social and an economic model for the enslavement of men (Biot, 1840; Tourmagne, 1880).

The most important of the early-twentieth-century theorists was H. J. Nieboer (1910), who broke with the evolutionists with his open-resource theory. His work, which is still influential, was unusual also in its reliance on statistical data. His main hypothesis was that slavery existed to a significant degree only where land or some other crucial resource existed in abundance relative to labor. In such situations, free persons cannot be induced to work for others, so they must be forced to do so. The theory has had lasting appeal, especially for economic historians, since it is both testable and consistent with marginal utility theory. It was revived by Baks (1966) and by the MIT economist, Domar (1970). However, the theory has been shown to have little empirical support from modern cross cultural data (Patterson, 1977b; Pryor, 1977); and Engerman (1973) has questioned seriously its theoretical consistency.

In the course of criticizing Nieboer and Siegel (1945) proffered a functionalist theory which claimed that chattel slavery may be expected to occur in those societies where there is a tendency to reinforce autocratic rule by means of wealth symbols, and where the process results in a rather strongly demarcated class structure. There is little empirical support for this theory, and it verges on circularity. In many pre-modern hierarchical societies with wealth symbols, it was slavery which was the main cause of increased stratification.

The best recent comparative work on slavery has come from historical anthropologists studying Africa. Meillassoux (1975, 1991) and his associates have demonstrated ably from their studies of West Africa and the Sahel just how valuable a nondogmatic Marxian approach can be in understanding the dynamics of trade, ethnicity, status, and mode of production in complex lineage-based societies. The anthropologist Jack Goody (1980), drawing on Baks (1966), began by arguing that 'slavery involves external as well as internal inequality, an unequal balance of power between peoples.' From this unpromising start he enriches his analysis with both the ethnohistorical data on Africa and the cross-cultural statistical data from the Murdock Ethnographic Atlas. Central to his analysis is the role of women. The complex facts of slavery cannot be explained, he argues, 'except by seeing the role of slaves as related to sex and reproduction as well as to farm and production, and in the case of eunuchs, to power and its non-proliferation.' While being valuable, Goody's arguments are confined to Africa, and even with respect to this continent they are insufficient to explain why it was that some African societies came to rely so heavily on the institution while closely related neighboring groups did not.

The economist Frederic Pryor (1977) has come closest to formulating a general theory of premodern slavery using modern statistical techniques applied to cross-cultural data. He distinguishes between social and economic slavery, and argues that different factors explain the presence of one or the other. Central to his theory is the nineteenth-century idea that there is a correspondence or 'homologism' between male domination of women and masters' domination of slaves. He tried to demonstrate that economic slavery was most likely to occur 'in societies where women normally perform most of the work so that the slave and the wife act as substitutes for each other,' whereas social slavery was related to 'the role of the wife in a polygynous situation.' The theory is interesting and robustly argued but is problematic. Where women dominated the labor force there was no need for men to acquire slaves for economic purposes. On the contrary, it was precisely in such situations that slaves, when used at all, were acquired for social purposes. The presumed correspondence between wives and slaves is also questionable. There were profound differences between these two roles. Wives everywhere belonged to their communities, and were intimately kin-bound, whereas slaves everywhere were deracinated and kinless. Wives always had some rights, some power, at least in the protection of their kinsmen, in relation to their husbands and could rarely be killed with impunity, which was not true of slaves. Wives everywhere had honor, while slaves had none.

Far more comparative work is needed for an understanding of the institutionalization of slavery. The main variables involved in any explanation are now well known. They are: The economic and social role of women; polygyny; internal and external warfare; the mode of subsistence (mainly whether pastoral or agricultural); and the mode of political succession. However, the causal role and direction of each of these variables is complex, and their interaction with each other even more so. To take the role of women as an example, in some cases it is their role as producers that is important; in others, their role as reproducers. It is also difficult using static cross-cultural data to ascertain whether low female participation in production is the result of slavery or its cause.

Approaches to the Study of Genuine Slave Societies

Marxist scholars were the first to take seriously the problem of the origins, nature, and dynamics of large-scale slavery (for a review, see Patterson, 1977a). Engels's (1962) periodization view that large-scale slavery constituted an inevitable stage in the development of all human societies was merely one version of nineteenth-century evolutionism, discussed earlier. It dominated East European thought until the deStalinization movement, and is still the orthodox view in mainland China.

More sophisticated, but no less problematic, have been attempts of modern Marxists to formulate a 'slave mode of production.' The most empirically grounded of these attempts is that of Perry Anderson (1974) who argued that 'the slave mode of production was the decisive invention of the Graeco-Roman world, which provided the ultimate basis both of its accomplishments and its eclipse.' There is now no longer any doubt that slavery was foundational for both Athens and Rome, and that these were the first societies in which large-scale or genuine slavery emerged. However, the concept of the 'slave mode of production' overemphasizes the materialistic aspects of slavery, making it of limited value for the comparative study of slavery. Slaves were indeed sometimes used to generate new economic systems – as in Rome and the modern plantation economies – but there are many cases where, even when used on a large scale, there was nothing innovative or distinctive about the economic structure. The

narrow materialist focus not only leads to a misunderstanding of the relationship between slavery and technology in the ancient world, but more seriously, it fails to identify major differences between the Greek and Roman cases, and it is of no value in the study of genuine slave societies in which the structurally important role of slaves was noneconomic, as was true of most of the Islamic slave systems.

Several non-Marxist historical sociologists, drawing also on the experience of ancient Europe, have made important contributions to our understanding of genuine slave societies. According to Weber (1964) slavery on a large scale was possible only under three conditions: '(1) where it has been possible to maintain slaves very cheaply; (2) where there has been an opportunity for regular recruitment through a well-supplied slave market; (3) in agricultural production on a large scale of the plantation type, or in very simple industrial processes.' However suggestive, there is little support for these generalizations from the comparative data. Medieval Korea (Salem, 1978) and the US South (Fogel and Engerman, 1974) disprove (1) and (2). And work on urban slavery in the modern world as well as the relationship between slavery and technology in the ancient world disprove (3) (Finley, 1973).

Finley (1960, 1973, 1981) was the first scholar to grapple seriously with the problem of defining genuine slave societies, which he explicitly did not confine to those in which the slaves were economically important. He also cautioned correctly against too great a reliance on numbers in accounting for such societies. His emphasis on the slave as a deracinated outsider led him to the conclusion that what was most advantageous about slaves was their flexibility, and their potential as tools of change for the slaveholder class. Finlay also offered valuable pointers in his analyses of the relationship between slave and other forms of involuntary labor. And in criticizing Keith Hopkins's (1978) conquest theory of the emergence of genuine slave societies, persuasively he encouraged an emphasis on demand, as opposed to supply factors in the rise of slave society. Romans, he argued, captured many thousands of slaves during the Italian and Punic wars because a demand for them already existed and 'not the other way around.' He postulated three conditions for the existence of this demand: private ownership of land, and some concentration of holdings; 'a sufficient development of commodity production of markets'; and 'the unavailability of an internal labor supply.'

A Framework for the Study of Slave Societies

It is useful to approach the comparative study of slave society with an understanding of what structural dependence means. There are three fundamental questions. First, what was the *nature* of the dependence on slavery; second, what was the *degree* of dependence; and third, what was the *direction* of dependence. Answers to these three questions together determine what may be called the *modes of articulation* of slavery.

The nature of dependence on slavery may have been primarily economic or social, political or militaristic, or a combination of these. Economic dependence was frequently the case, especially in ancient Rome and in the modern capitalistic slave systems. Here the critical questions are: What were the costs and benefits of imposing and maintaining an economy based on slave labor? Stanley Engerman (1973) has written authoritatively on this subject. He distinguishes between the costs of imposition, of enforcement, and of worker productivity. Lower maintenance costs, more constant supply of labor, greater output due to the neglect of the non-pecuniary costs of labor, higher participation rates and greater labor intensity, and economies of scale, are the main factors proposed by Engerman in explaining the shift to slave labor. They apply as much to ancient Rome as they do to the modern capitalistic slave systems of America and the Caribbean.

Military and bureaucratic dependence were the main noneconomic forms, and they could be as decisive for societies as was economic dependence. The rise of Islam was made possible by the reliance on slave soldiers, and the Abbasid Caliphate, along with other Islamic states, was maintained by slave and exslave soldiers and bureaucrats. Although there was little economic dependence on slaves in most Islamic states – with the notable exception of ninth-century Iraq – many of them qualify as genuine slave societies as a result of the politico-military dependence of these regimes on slavery, and the ways in which slaves influenced the character of their cultures, many of the literati also being slaves or descendants of slaves (see Pipes, 1981; Crone, 1981; Marmon, 1999).

The degree of dependence must be taken into account, although it is sometimes difficult to quantify. There has been a tendency to emphasize the size of the slave population over other variables, and while demography is important it can sometimes be misleading. Thus, it has been noted that no more than one in three adults were slaves in Athens at the height of its slave system in the late fifth-century BCE as a way of playing down the importance of slavery. But as M. I. Finley liked to point out, the same was true of most parts of the American Slave South, and no one has ever questioned the fact that it was a large-scale slave system.

Finally, there is the direction of dependence. Even where a society had a high functional dependence on slavery it was not necessarily the case that slavery played an active, causal role in the development of its distinctive character. The institution, though important, was not structurally transformative. In ancient Rome, the Sokoto Caliphate and the slave societies of the Caribbean, the American South and Brazil, slavery was *actively articulated* and transformative. In other cases, however, it was *passively articulated*, the classic instance being Korea during the Koryo and Yi periods where, although a majority of the rural population were at times slaves, there was no significant transformation of the economy, and no impact on the regime's government and culture. The same was true of several of the modern Spanish colonies of Central and South America. During the sixteenth and seventeenth centuries there was marked structural dependence on slavery in Mexico and Central America as well as Peru, and the urban areas of Chile and Argentina, but the institution was not determinative in the course of development of these societies and, as in Korea, when slavery ended it left hardly a trace, either cultural or social (Mellafe, 1975; Palmer, 1976; Klein, 1986; Blackburn, 1997).

These three factors together determined a finite set of modes of articulation, which is a sociologically more useful construct than that of the so-called slave mode of production. Space permits only the most cursory mention of some of the most important such modes of articulation.

The *lineage mode of articulation* refers to those kin-based societies in which large-scale slavery was related critically to the rise to dominance of certain lineages in the process of class and state formation. In some cases, slavery originally served primarily economic ends; in others, mainly social and political ones; but in the majority the institution became multifunctional. This kind of genuine slave society was most commonly found in western and west-central Africa. Warfare, combined with some critical internal factor such as demographic change accounted for the rise of slavery (see Miller, 1977 for the Kongo kingdom). The ideal case of this mode of articulation was the Asante state (Wilks, 1975; Klein, 1981). Slaves were originally incorporated as a means of expanding the number of dependents, a tendency reinforced by the matrilineal principle of descent. The growing number of slaves enhanced the lineage heads who owned them, and facilitated the process of lineage hierarchy and state formation. Later, the role of slaves was greatly expanded to include a wide range of economic activities, including mining.

The *predatory circulation mode* refers to those slave societies in which warfare and raiding mainly for slaves were the chief occupations of a highly predatory elite. The warrior class was usually assisted by a commercial class which traded heavily in slaves. There was usually a high rate of manumission of slaves, who not only contributed to the production of goods, but in their role as freedmen soldiers helped the ruling class to produce more slaves. Thus there was a continuous circulation of persons in and out of slave status as outsiders were incorporated as loyal freedmen retainers, creating a constant need for more enslaved outsiders. Slaves and freedmen often played key roles in, and sometimes even dominated, the palatine service and elite executive jobs.

The contiguous existence of pastoral and sedentary agricultural peoples with different levels of military might was the major factor in the development of this mode of articulation of slavery. The mode is strongly associated with Islam, and there are many examples of it in the Sahel and North Africa. The west–east spread of the Fulani over an area of some 3000 miles over a period of 800 years provides one of the best cases of this mode, on which there is an abundance of historical and anthropological data (Lovejoy, 2000; Pipes, 1981; Meillassoux, 1975, 1991).

The *embedded demesne mode* embraces those patrimonial systems dominated by large landed estates in which slaves were incorporated on a substantial scale to cultivate the demesne land of the lords. Serf or tenant laborers continued, in most cases, to be the primary producers of food for the society, and their rents or appropriated surpluses remained a major source of wealth for the ruling class. However, slaves were found to be a more productive form of labor on the home farms of the lords for the cost–benefit reasons analyzed by Engerman, mentioned above. The landowners got the best of both types of labor exploitation. This was a particularly valuable arrangement where a landed aristocracy needed to change to a new crop but was not prepared to contest the technical conservatism of serfs; where there was a supply of cheap labor across the border; or where there was a high level of internal absenteeism among the landed aristocracy.

This is the least understood or recognized form of advanced slave systems, perhaps because its mode of articulation was usually passive. Many of them were to be found in medieval Europe, especially in France, Spain, and parts of Scandinavia (Dockes, 1982; Verlinden, 1955, 1977; Bonassie, 1985; Anderson, 1974; Patterson, 1991). The slave systems of the western 'states' of eleventh-century England, where slave populations were as high as 20% of the total are likely examples. So, possibly, was Viking Iceland, which may well have had similar proportions of slaves (Williams, 1937; Foote and Wilson, 1970). However, the ideal case of embedded demesne slavery was to be found in Korea, especially during the Koryo and early Yi periods. Here the slave population sometimes exceeded that of other forms of bonded labor (Salem, 1978; Wagner, 1974; Hong, 1979).

The *urban–industrial modes* of articulation were those in which the urban elites came to rely heavily on slaves for support. Slaves played a relatively minor role in agriculture, although they may well have dominated the 'home farms' of certain segments of the ruling urban elites. Slave labor was concentrated in urban craft industries which produced goods for local consumption and exports, as well as the mining sector where it existed.

Slavery emerged on a large scale in such systems as a result of a combination of factors among which were the changing nature and frequency of warfare, conquest of foreign lands, the changing tastes of the ruling class, crises in the internal supply of labor, shifts in food staples, growing commercial links with the outside world, and demographic changes.

This mode of articulation could be either passive or active. To the extent that the character of the urban civilization depended on its urban economy, and to the extent that the economy depended on slave laborers, both manual and technical, to that degree were these systems active in their articulation. The classic case of the active mode of slave articulation were the ancient Greek slave systems, especially Athens of the fifth- and fourth-centuries BC (Finley, 1981; Garlan, 1982; De Ste. Croix, 1981). Typical of the passive mode of urban–industrial articulation were several of the Spanish slave systems of Central and South America during the sixteenth and seventeenth centuries, mentioned above.

The *Roman or urban–latifundic mode:* ancient Roman slavery stands in a class by itself, having no real parallels in either the ancient, medieval, or modern worlds. It came the closest to a system of total slavery in world history. It was distinctive, first, in the sheer magnitude of its imperial power and the degree of dependence on slavery, both at the imperial center and in its major colonial sectors. Second, Rome was unique in the extent of its reliance on slavery in both its rural and urban–industrial sectors. Third, the articulation of slavery was more actively transformative than in any other system, entailing what Hopkins (1978) called an 'extrusion' of free, small farmers and their replacement by slaves organized in gangs on large latifundi. Rome was unusual too, not only for its high levels of manumission, but for the extent to which slaves and slavery came to influence all aspects of its culture.

The *capitalist plantation mode:* contrary to the views of early economic theorists such as Adam Smith, and of Marxist scholars until fairly recently (Genovese, 1965), modern plantation slavery was in no way incompatible with capitalism. Indeed, the rise of capitalism was intimately bound up with this mode of articulation of slavery, and at its height in

nineteenth-century America was as profitable as the most advanced industrial factories of Europe or the northern United States (Fogel and Engerman, 1974). Plantation slavery constituted one version of the worldwide systemic spread of capitalism, in which capital accumulation was advanced through the use of slaves in the peripheral colonial regions, complementing the use of so-called free labor in the metropolitan centers, and of serf and other forms of dependent labor in the semiperipheral areas of Eastern Europe and Latin America (Wallerstein, 1974; Blackburn, 1997).

While plantation slavery bore some organizational resemblance to the ancient slave latifundia, and indeed can be traced historically to late medieval and early modern variants of the ancient model (see Solow, 1991), it was distinctive in its complex, transnational system of financial support, in its production for international export, its heavy reliance on a single crop, its advanced organizational structure, which in the case of sugar involved innovative agri-industrial farms, in the vast distances from which slaves were imported, entailing a complex transoceanic slave-trading system, and in its reliance on slaves from one major geographic region who differed sharply from the slaveholding class in ethnosomatic terms.

However, it is important to recognize that there existed concurrently with the capitalistic plantation mode several other modes of slave articulation that were either precapitalist or at best protocapitalist. As has already been noted, many of the Spanish colonial systems in the Americas relied on forms of slavery that were nonaccumulative and distinctly premodern in their articulation, for example the urban–industrial modes of Mexico and parts of South America which were focused heavily on mining. In the Spanish Caribbean up to the third quarter of the eighteenth century a peculiar premodern form of agri-pastoral slavery prevailed which had little in common with the highly capitalistic slave plantation systems of the neighboring French and British islands, and which had to be dismantled at considerable political and socioeconomic cost in order to make way for the belated capitalistic slave systems that were imposed forcefully during the nineteenth century (Knight, 1970).

While slavery was largely abolished in the Americas through the course of the nineteenth century (Blackburn, 1988; Davis, 1975), pockets of the institution persist into the twenty-first century in northern Africa and parts of Asia (Stearman, 1999). With the possible exception of Mauritania, however, in none of these societies do we find genuine slave systems. It can be claimed, with cautious optimism, that this most inhuman form of societal organization has vanished from the world.

Abstract

Slavery has existed for millennia. It is both a status – an inferior person with no rights in a society – and a condition, a kind of humanity which was accorded fewer rights than other forms of humanity. A slave was the quintessential outsider. Most societies had slaves but only some societies – ancient Greece and Rome and the plantation colonies of European powers in the Americas – were slave societies in which slavery was essential to the economy and politically sensitive. In modern times, slavery has been strongly connected with race, especially the forced removal of Africans to the Americas to labor in the production of tropical goods.

"O what a rogue and peasant slave am I", William Shakespeare has Hamlet, the doomed Prince of Hamlet exclaim at the end of Act 2 of 'Hamlet'. Hamlet is a prince and so was almost as far removed from an actual slave as it is possible to be. Moreover, neither in Denmark, where the play is set, nor in early seventeenth century England, where the play was performed, was slavery common. But the idea of slavery, as Shakespeare recognized, was well-known even in places where a person would seldom meet a slave let alone become a slave oneself. Shakespeare used the imagery of slavery to get at a deeper truth. To be a slave or to feel like a slave, was to be in the pit of despair because no condition could be worse than being a slave. Slavery was a form of exploitation in which one human was owned by another person and in which the slave hovered uncertainly between the contradictory positions of being both a piece of property and also a person. It was also, as imaginative artists since Aristophanes and thinkers beginning with Aristotle have realized, a state of mind; a status that affected how one thought of oneself, if one was a slave, and how others thought of slaves.

Slavery comes in many culturally specific forms. Common to all these different forms is the fact that slaves are denied the most basic rights. Slaves remain outside the social contract that binds the other members of a given society; they are people without honor and kin, subject to violent domination. They are objects of the law, not its subjects, considered as property or chattel. Hence, we may describe slavery (with Orlando Patterson) as a form of 'social death', and slaves as outsiders kept in a position of institutionalized marginality. Historians accept part of Patterson's concept but are wary of being too dogmatic in seeing slaves as 'socially dead', because such a view tends to deny agency to slaves and tends toward accepting the view often put forward by the master class that enslaved people were akin to beasts or nonhuman property. The trend at present is to see slavery less as a form of social death than as a negotiated relationship. In this relationship masters had most of the power but their power was always contested by enslaved people who had their own imperatives that often conflicted with their masters' desires. Enslaved people formed their own communities with value systems and forms of behavior that differed from the social norms of nonenslaved people; but these communities were set within larger social groupings that exerted their own pull over enslaved people's desires. If slaves were legally 'socially dead' this death was more a legal fiction than a reality. As a host of historians have argued in the last decade, slaves fashioned lives full of meaning for themselves even in the direst circumstances of want and physical and psychological oppression (Patterson, 1982).

Slavery is tied up less with law than with custom. The slave was the quintessential outsider, no matter how dependent a society was on the slaves' labor. That status of outsider was sometimes based on ethnicity, sometimes race, and sometimes residence. In many languages, for example, the term for foreigner also denoted slaves. Nowadays, slavery is considered a most inhumane practice. The United Nations Universal Declaration of Human Rights proclaims: "No one shall be held in slavery or servitude; slavery and the slave trade shall be prohibited in all their forms". Signing the slavery conventions of 1926 and 1956, 122 states have committed themselves to abolish slavery and similar practices such as debt bondage, serfdom, servile marriage, and child labor (Bales, 1999).

In historical times, however, slavery as an institution was accepted in many societies, from early Mesopotamia and Pharaonic Egypt to ancient China, Korea, India, medieval Germany, and Muscovite Russia; from the Hebrews to the Aztecs and Cherokees. Indeed, slavery was a commonly accepted practice throughout Biblical societies and times, and is mentioned favorably as a social practice in both the Old and New Testaments. Nevertheless, according to classical historian Moses Finley there were only five full-fledged slave societies with slaves constituting the majority of people and their work determining the whole economy. All five were located in what we tend to call the West; two in antiquity – Athenian Greece and Rome between the second century BC and AD fourth century; and three in modern times – Brazil, the Caribbean, and the Southern United States. Slavery did exist elsewhere. The Ottoman Empire, for example, was notorious for its slave soldiers, the Janissary, taken from its Slavic neighbors to the North and from Africa. But it was only in the five societies noted above that slavery became the dominant institution in society, shaping all social, economic, and legal relationships. Finley's major contribution to the history of slavery came with his distinction of 'slave societies', such as ancient Greece and pre-twentieth century Brazil, where everything was affected by

slavery and the multitude of societies in which slavery existed but did not form the essential bulwark of social and political life. Most histories of slavery concern 'slave societies' rather than 'societies with slaves'; but many people lived in 'societies with slaves' and often attitudes to slavery were shaped, most of all, in such societies where slavery existed but was of marginal importance. Eighteenth century Western Europe and the Northern colonies of British North America were societies with slaves, rather than slave societies. It was in these societies that the morality of slavery was questioned for the first time. Thus, when discussing the history of slavery we need to also consider antislavery, or attempts to make slavery not normative but peculiar (Davis, 1984; Finley, 1987).

Slavery until the late eighteenth century was so normal as to be almost universal. It was so common that few people thought about whether it was right or wrong. Nevertheless, slavery always attracted historical attention – from Aristotle in ancient times to contemporary commentators. Slavery may be illegal in the twentieth century but millions of people in Asia and Africa still labor in conditions that can only be called slavery. Before the mid-eighteenth century most writers followed Aristotle in thinking of slavery as mostly a positive good, adding to the sum of human happiness even if unfortunate for those caught up in this institution as slaves. Aristotle justified slavery on four grounds. One was racist. He believed that Easterners were intelligent but soft and Northerners were strong and stupid. The latter were ideally suited to hard work but needed to be coerced to do so since they were naturally lazy. They could only be forced to work through coercion and their strength needed to be controlled through the application of extreme force when they disobeyed their owners. It was easy for Europeans to extend this analysis to Africans when after the sixteenth century it became problematic to enslave people of European descent. The second assumption was related to the first: some people had to be controlled for their own good. Just as children had to obey parents, so too it was good if inferior people accepted the commands of their intellectual superiors. Aristotle's third reason was tautological. Once people became slaves they adopted slavish behavior, thus justifying treating them as slaves. Southern slave owners were very fond of this kind of reasoning. Finally, slavery was necessary because without slavery work would not get done. In the plantation colonies of the Caribbean and Brazil such reasoning had great purchase. Working as laborers producing tropical goods, notably sugar, was so disagreeable that no one would do it if they had a choice to be involved in some other activity (Davis, 1966).

Aristotle's defense of slavery prevailed, more or less, as the major historical interpretation of slavery, until the mid-eighteenth century, when for the first time a genuine anti-slavery movement emerged. Ironically, it emerged at the time when the Atlantic slave trade ferrying captive Africans to the Americas was at its height and when plantation slavery in the Americas was most profitable and most important for European prosperity. The writers who began to question slavery, starting with Montesquieu and increasingly including all Enlightenment thinkers, came to question slavery as part of an overall critique of commercial society. Taking their cues from Greece, Rome, and Medieval European experiences, they tended to interpret slavery as an intermediate stage in the general process of historical development. G.W.F. Hegel construed slavery as a sort of development aid for the benefit of Africans. Classical social scientists from Adam Smith to Max Weber identified slavery with backwardness. Marxist thinkers were even more explicit, positing primitive society, slavery, feudalism, capitalism, and communism as five consecutive stages of world history. Thus, slavery and capitalism, slavery and markets, and slavery and technological innovations were considered utterly incompatible (Burnard and Heuman, 2010; Blackburn, 1997).

Studies of US and West Indian slavery have dominated the field of slave studies from its very beginning, although this dominance is beginning to change as scholars start to focus more on Africa and Europe as the places where forms of slavery were first established (Eltis, 2000; Thornton, 1992). Nevertheless, scholars of US slavery, in particular, have set the agenda for research into other domains, such as the transatlantic slave trade and its precedents in the Mediterranean and the Black Sea during the Middle Ages and the Renaissance; and slavery in the Indian Ocean world and in Muslim Africa (Genovese, 1974). Studies of classical slavery have been less dependent on models drawn from studies of New World slave systems. The dominance of studies of US slavery in the historiography of slavery has been unfortunate, because the model for slavery became the Antebellum Southern slave plantation, which was by any terms, highly aberrant within the long history of slavery. Until recently, slavery was treated in essentially ahistorical terms – as an institution that varied little over time and place and about which grand generalizations could be made. The dominant trend in recent historiographies of slavery has been to place slave societies very much in the context of their times. Ira Berlin has been the prime exponent of the necessity of treating slavery as a highly variable institution. Slavery was different when it was first established, when the laws around slavery were uncertain, from what it became once the plantation system had been fully established in the early eighteenth century; and it was different again when the age of revolutions and the abolition of the slave trade in the late eighteenth century focused attention on whether it was moral to deprive individuals and their descendants of their liberty, no matter how valuable their work was to European and American prosperity (Berlin, 1998).

The first historians of slavery tended to be slave apologists. U.B. Phillips may be taken as representative of a larger trend. Writing in the early years of the twentieth century, Phillips argued that despite occasional cruelties, slavery in the United States was mostly benign and indeed was well suited to people of African descent as a result of their innate capacities (Phillips, 1918). Historians have had to fight against the racism that has been implicit in much of the early study of slavery and have had to try, in particular, to write against sources in which evidence was filtered through a lens conditioned by racist prejudice, especially against Africans. The first changes in approach to slavery came after World War II, when scholars such as Kenneth Stampp tried to treat slavery on its own terms. His work tended to stress to an unusual degree the brutality and exploitative nature of slave life in Antebellum America. For some scholars, this brutality reminded them of very recent events, notably Nazi outrages in Eastern Europe against the Jews (Stampp, 1956). Slavery studies took a turn that eventually proved unproductive. Stanley Elkins argued that slavery

should be seen as a quasi-Nazi institution, as a close system of generalized violence and totalitarian control with dehumanizing effects similar to Nazi concentration camps. For Elkins and for other historians in the 1950s and 1960s, slaves were victims, devoid of any power or will of their own. Elkins' efforts at psychological speculation on how slaves coped with brutalization and from the despair of living in a closed system, ultimately were an unprofitable scholarly detour. It has had the unfortunate effect of suggesting that it was not just that slaves were victims but that the slave system was akin to what happened in concentration camps, with slaves having no hope of gaining any psychic maturity (Elkins, 1968). Such an interpretation was not what scholars intended. The result of this approach to slavery (and also the works of econometrists such as Robert W. Fogel and Stanley W. Fogleman, whose much-heralded economic survey of Antebellum Southern slavery in 1974, suggested that slavery was, contra to Adam Smith, an inherently profitable institution) was to suggest both that slavery was not that terrible and also that enslaved people were so under the control of their masters that their very personalities were deformed. Ironically, the historiography of the late 1960s and early 1970s in the United States replicated the kinds of ideas that Antebellum slave holders themselves said characterized enslavement (Fogel and Engerman, 1974).

Ever since that moment in the historiography of slavery, scholars have concentrated on restoring slave agency to the history of slavery. Slavery came to be seen as a negotiated relationship and as an intrinsically unstable process, the terms of which varied with time and place. This process spanned different stages from enslavement and transportation to life in slavery and possible, yet by no means inevitable, social reintegration. There were different ways to overcome the outsider status: resistance and flight, manumission, or the purchase of freedom. Prompted by the American Civil Rights Movement, slave lives, slave culture, and slave resistance developed into privileged subjects of study. Herbert G. Gutman showed that slaves against all odds were living in families, creating enduring networks of kinship and self help (Gutman, 1976). Religion proved to be another major sphere where slaves gained some cultural autonomy. Integrating Christian teachings and African beliefs they developed a richly textured religious life with dance and song as integral parts of worship. The patterns of slave life became a major object of study, with Philip D. Morgan's comparison of eighteenth century South Carolina and Virginia being the best example yet of a comprehensive and sensitive portrait of the numerous ways in which slaves created lives for themselves separate to their masters (Morgan, 1998). Other scholars have focused on resistance, arguing not only that slaves continually resisted the terms and conditions of their enslavement, but also that their resistance was pivotal in shaping important political events such as the Age of Revolutions – a period in which the Haitian Revolution, the only successful slave revolt in history, is increasingly important (Dubois, 2004).

One major theme in the study of slavery has been the effort to determine the numbers of people who were involved in various slave trades. The most determined efforts have been focused on the Atlantic slave trade from West Africa. Philip D. Curtin was the first to attempt a census of the transatlantic slave trade using customs records from the Americas (Curtin, 1969). His calculations have later been complemented and refined, most notably in the Transatlantic Slave Trade Database, a comprehensive accounting of the great majority of voyages that crossed the Atlantic between the fifteenth and nineteenth centuries (Eltis, 2008). Curtin did not have the advantage of later scholars in being able to utilize digital methodology to establish precise numbers, yet his general insights have stood remarkably well. Others tried to extend his census to the older, established Trans-Saharan, Indian Ocean, and Red Sea trades (Vaughan, 2005). Scholars reconstructed slave prices at the points of purchase and sale, carefully tracing changes over time and studying all the other aspects of slave trading and the plantation business. These endeavors engendered seminal new insights. Scholars were able to prove that the length of a voyage was the single most important factor determining mortality during the voyage across the sea, the ghastly Middle Passage, with death rates ranging from 10 to 20%. They showed that pricing was competitive and that supply was responsive to changes in price and that the transatlantic slave trade continued well into the nineteenth century. It ended when Brazil and Cuba emancipated their slaves in the 1880s, the last nations to do so in the Western hemisphere. Scholars also discovered that markets shifted Eastward and Southward along the West African coast, from Senegambia and the Upper Guinea coast to the Bight of Biafra and Northwestern Angola. Imports into Africa varied over time and from place to place, with cotton goods, brandy, guns, and iron tools in high demand everywhere along the coast. With the recent publication of more than 27 000 Atlantic slave trading voyages in one single data set, even nonspecialists have access to parts of the evidence used in the econometric computations. Taken together, studies of the new economic history show that the Marxist thesis that there is an inherent contradiction between slavery and capitalism is untenable, because both slave trading and plantation economies were capitalist to the core, with prices set by the laws of supply and demand (Eltis, 2008; Byrd, 2008; Clarence-Smith, 1989; Manning, 1990; Rediker, 2007).

A major contentious issue among scholars has been the significance of slavery for the Industrial Revolution. In 1944, Eric Williams argued that the profits from the 'triangular trade' had financed the British Industrial Revolution, adding that abolition was a consequence of economic decline (Williams, 1944). This double-pronged 'Williams thesis' became a central tenet of Dependency theory. A close look at hundreds and thousands of slave voyages, however, showed that average profits were smaller than scholars had previously assumed and could never explain why Britain achieved self-sustained industrial growth in the latter half of the eighteenth century. New data on capital formation in that period points in the same direction. Nevertheless, slavery and the plantation economies contributed to British economic growth and the advent of modernity. Slavery reduced the cost of sugar and tobacco for European consumers. It made great fortunes for a few planters and merchants. It also created markets for cheap industrial mass-products. Indeed, sugar plantations with their gang-labor system were 'factories in the fields' with a work discipline prefiguring that of modern industrial plants. The impact of slavery was also felt in the realm of ideas and ideology. It furthered a racially informed negative perception of all things African in the West; and set

the stage for systematic racism against people of African descent (Drescher, 1977).

Recent scholarship has diminished the importance of Antebellum America as the place where slavery was most important. Indeed, the recent turn toward Atlantic history has illustrated that the Antebellum South was indeed a peculiar place, not just in nineteenth century America but in slavery generally. Most Atlantic slave societies did not reproduce themselves naturally, unlike the antebellum South; meaning that they relied on constant inputs of fresh captives from Africa in order to survive. The center of slavery studies has moved backward in time – from the nineteenth to the eighteenth century – and has moved southward, to the Caribbean and Brazil. Most importantly, the key place shaping slavery was Africa. The impact of slavery on Africa has been much debated. An earlier generation of scholars with firsthand experience of colonial domination saw African societies mainly as victims of external forces. They singled out the transatlantic slave trade as a first step toward underdevelopment, as it depopulated whole areas, (or so ran the argument) and induced African rulers to engage in wars for the sake of taking prisoners for sale in exchange for guns, which then triggered new wars. This set of ideas informed Dependency theory as well as world-system analysis and early nationalist African historiography. Walter Rodney even argued that African slavery on the Guinea coast was a result of external demand (Rodney, 1982).

Increased attention to what happened in Africa has changed these assumptions. Scholars such as John Thornton have shown that to understand the Atlantic slave trade means understanding African economics and politics, because it was Africans who controlled the trade, not Europeans (Thornton, 1992). Moreover, just as Europe is a diverse continent, so too was Africa. To understand slavery, it is necessary to understand African diversity, over both space and time. To stay in business, European and American slave traders had to adapt to local circumstances. They were at the mercy of local merchants and local power holders. They hardly ever ventured beyond the ports of call and the forts they built along the West African coast. They also bought women and children, (although the planters considered them a second choice to men), as well as people from areas other than those that the planters preferred. Women constituted up to a third of the slaves sent to the Americas. The female ratio among slaves was higher than among early European immigrants. It ensured an enduring African physical presence (Lovejoy, 1983).

Studies of African slavery have furthered the understanding of these cultural parameters. Slavery was widespread in precolonial Africa and expanded in the nineteenth century despite, or rather because of, the abolition of the transatlantic slave trade by the UK in 1807. Some scholars even argue that West African societies then developed into fully fledged slave societies with 50% and more of their population kept in bondage. First among these were the Sudanic societies from the Futa Jallon to Sokoto and Adamawa, where Islamic revolutions and state-building initiated more intense slave trading than ever before. Yet, African slavery, often referred to as 'household slavery', was markedly differed from chattel slavery. As elsewhere, slaves had to do the hardest work and their owners treated them as outsiders, the first to be sacrificed in public rituals and put to death at the whim of their owner. Nevertheless, it was common to find slaves in positions of albeit borrowed authority, such as traders, officers, and court officials. Elsewhere slave and slave owner worked side by side. Alternatively, slaves lived in villages of their own. They owned property and in some cases, even slaves of their own. More importantly, the slave status was not a fixed status; rather it changed over time along a slave to kinship continuum, with people born into slavery exempt from further sale. Recent scholarship has stressed that women were the preeminent victims of slavery in Africa as they were valued for their labor power and for the offspring they might give birth to. Moreover, one should never forget that power and prestige in African societies depended on the number of followers a person could count on, rather than on the control of land which was not a scarce resource yet, or at least,not everywhere (Lovejoy, 1983; Meillassoux, 1991).

Colonialism has helped to keep the memory of slavery alive in postcolonial societies, from the United States to Brazil, to the Caribbean, and to Africa. In the early nineteenth century, Britain had done its best to end the slave trade. It even stationed a naval squadron for this purpose in West African waters and concluded antislave trade treaties with African rulers who had trouble seeing the benefits of abolition. The European public sometimes saw the imperialist scramble for Africa as an antislavery crusade; but colonial administrations, while forcefully suppressing the slave trade, were reluctant to fight slavery as a social system; rather they closed their eyes and did their best to freeze existing social relations while claiming to bring progress to Africa. When slavery finally ended in Africa, it did so not so much as the result of conscious acts of emancipation but rather because of the emergence of a colonial labor market, with the socially defined older mechanisms for the integration of outsiders easing the transition. The men and women held in bondage eagerly took up alternatives wherever they were viable.

Whereas studies of slavery have become ever more detailed and localized, historians have come to realize that the Middle Passage is more a bridge rather than an abyss or a one-way street, binding different cultures together, a point first made by the anthropologist Melville J. Herskovits (Herskovits, 1941). Slaves came with a history of their own to the Americas; returning Africans and children of former slaves such as Olaudah Equiano, Wilmot Blyden, and James Africanus Horton were among the first to consciously define themselves as Africans. Hailing from different regions of Africa, yet sharing a common plight, they developed an awareness of a common African identity. The books they wrote helped to lay the foundations for Pan-Africanism, a strand of ideas and a political movement central to the freedom struggle of Africans in the twentieth century.

David Brion Davis noted a similar correlation between slavery and freedom in Western religious, legal, and philosophical discourses (Davis, 1966). Hence the double paradox and legacy of slavery: it inflicted death and hardship on millions and millions of people of mostly African descent for the benefit of a few; and while it was instrumental for the rise of racial prejudice, it also shaped the notion of freedom and equality as we know and cherish it today. To consider these global dimensions is the challenge of any further research into the history of slavery, even when dealing with very specific local aspects of the problem. But this is easier said than done because

it requires historians to venture beyond the deeply rooted traditions of privileging the history of a particular nation-state, usually their own, into the open sea of a new comparative history. The fight against slavery is not won so long as debt bondage, servile marriage, forced labor, child labor, trafficking of women, forced prostitution, and other forms of bondage exist in many societies, including the rich countries of the West (Sweet, 2004).

Sleep and Health

Abstract

Sleep is a vital phenomenon, which fulfills essential functions in human development and affects life as a whole. Sleep-related problems are, therefore, important risk factors for ill-health and affect health at all ages. Factors that affect and are associated with sleep and sleep disturbances are, for example, short sleep, demographic characteristics (age, partnership status, or problems), health conditions (physical activity, obesity), stress, mental disorders, environmental factors, and quality of life. In many cases the reciprocal association between these factors and disturbed sleep makes it difficult to establish cause–effect relationships. Only longitudinal studies will make it possible to shed light on the processes linking sleep and health.

In terms of health behaviors, nutrition, exercise, or stress are widely discussed, whereas sleep in its fundamental role for health is often underestimated. Nevertheless, sleep is vital to physical and mental health, although the exact nature of the relationship between sleep and health remains elusive. Many factors affect the presumed causal link between sleep and health, which are likely to be reciprocal. Several risk factors for sleep disturbances and health impairments, however, have been established. One important first question to ask is what constitutes healthy sleep. Studies (e.g.,National Sleep Foundation) show that in adults, sleep duration should optimally vary between 6.5–9 h of sleep within a 24-h period (e.g., National Sleep Foundation), but it is important to mention that individual needs for sleep may vary substantially. Falling asleep within 15–20 minutes of lying down to sleep and to not have severe sleep interruptions is also considered to characterize healthy sleep, as is the absence of snoring, pauses in breathing, or other nighttime behaviors. Finally, one should feel rested when waking up and be able to be productive throughout the waking hours (National Sleep Foundation).

Variants of Sleep

Short Sleep

There is evidence from experimental studies linking short sleep with impaired appetite control and glucose regulation (Spiegel et al., 1999). In addition, a range of clinical studies have shown that decreased sleep is a risk factor for obesity and diabetes (Knutson and Van Cauter, 2008) and that it affects neuroendocrine stress systems (Meerlo et al., 2008). Decreased sleep duration is associated with poor performance (Van Dongen et al., 2003) and falling asleep at work (Ohayon et al., 1997). Whilst approximately 7 h of sleep is average in adults, there is a wide range in terms of individual sleep duration needed (Tucker et al., 2007). One may ask if it is sleep duration or quality of sleep that matters. When sleeping an average of 7 h a night, sleep quality is better related to health, affect balance, life satisfaction, and feelings of tension, depression, anger, fatigue, and confusion than average sleep quantity. Sleepiness has been shown to be more related to average sleep quality than sleep quantity (Tucker et al., 2007). In line with this, Tamakoshi and Ohno (2004) report that there is no epidemiological evidence that people who sleep 6 h per day and report no daytime sleepiness are at risk for poor health. Although short sleep duration or high variation of sleep has been linked to mortality, Kurina and colleagues (Kurina et al., 2013) found that the available literature does not provide consistent results supporting an association between self-reported sleep duration and mortality. Rather, fragmented sleep, for example caused by sleep apnea, decreases sleep quality and increases sleepiness (Marin et al., 2005).

Influencing Factors

Demographic Characteristics

Demographic characteristics (e.g., age, race, education, occupation, marital status) are also influences and are associated with sleep conditions and sleep problems. The next chapter will focus on age and partnership.

Age

Some research has been initiated covering a range of different age groups. Results show that sleep problems are common at all ages. In the first years of life, sleep duration problems are more common; in school-aged children and adolescents sleep onset problems are often mentioned, whereas with age many sleep-related changes occur. Some studies found that sleep in older people is less deep; they often have difficulties falling asleep, wake up more frequently during the night, awaken earlier in the morning, or report not being able to sleep. Over the last decades it was thought that the elderly need less sleep because of reduced daily activities. Nevertheless, subsequent studies with older people show that nearly 70% of elderly adults reported at least one sleep complaint, and 40% had two or more complaints (Reid et al., 2006). Older adults often change their circadian rhythm and have a high prevalence of sleep apnea and periodic limb movements. Objective tests show that older people are sleepy during the day (Dement et al., 1982). Excessive daytime sleepiness was the best predictor of poor mental and physical health-related quality of life (Reid et al., 2006). Furthermore, older people are often physically impaired, which can in turn affect sleep and sleep

quality (Laugsand et al., 2013). In addition, loneliness, resulting for example, from the loss of a partner, is associated with lower sleep efficiency (Cacioppo et al., 2002).

Partnership

Various studies have shown that marital quality is linked with sleep behavior. Hale (2005) collected data from more than 7000 adults. The study included sleep log data during a 24-h period, showing that unmarried adults were significantly more likely to report shorter sleep duration, compared to married adults. Interestingly, singles also more frequently report long sleep durations. These results show that singles are at high risk to be at the extremes of sleep duration, i.e., to either get too little or too much sleep, both of which are risk factors for poor health (Hale, 2005). In addition to the amount of sleep, some studies also provide evidence of a link between insomnia and lower levels of marital happiness (e.g., Troxel et al., 2009). Grandner et al. (2010) analyzed data of approx. 160 000 adults and found a significant association between marital status and sleep difficulties, such that the highest likelihood of reporting sleep difficulties was found in unmarried groups. Men or women who were divorced or never married had the highest risks (Grandner et al. 2010). Most of these studies are cross-sectional, however. Nevertheless, their results are in line with an earlier longitudinal study, showing that higher marital satisfaction predicted fewer insomnia symptoms, even after controlling for baseline sleep symptoms (Prigerson et al., 1999). Furthermore, Troxel et al. (2010) found in their 8-year longitudinal study of more than 350 adult women, lower sleep quality and longer nighttime awakenings in widows, whereas unmarried women showed longer sleep-onset latency and longer nighttime awakenings than married women.

Health Conditions

In addition to demographic characteristics, health conditions are strongly associated with sleep and sleep disturbances. The next section will focus on physical activity and obesity.

Physical Activity

Physical activity has been associated with better sleep than every other activity. Physical activity or exercise is typically recommended for better sleep by sleep experts (e.g., Lavie, 1996). When people are asked what helps them most to sleep well, more than 30% list exercise as the most important habit or practice (Urponen et al., 1988). But how much exercise is good for better sleep? Exercisers report better sleep than nonexercisers, even though they have the same amount of sleep each night (about 7 h). The study from 2003 (National Sleep Foundation, 2003) showed that people who exercise more frequently per week report fewer insomnia symptoms, less difficulties falling or staying asleep during the night, and lower daytime sleepiness. Furthermore, they wake up more refreshed and rested than people exercising less than once a week. Moreover, in this study, a dose–response pattern was found. People who exercised a minimum of three times per week reported better sleep than those who reported exercising one to two times per week. These results of the National Sleep Foundation study are based on more than 1500 adults showing strong associations of exercising with better sleep. In addition, the study published in 2013 (National Sleep Foundation, 2013) showed that more than 75% of exercisers reported as having good sleep quality compared to 56% of nonexercisers.

Studies with objective measurements show a diverse range of results. While many studies (e.g., Loprinzi and Cardinal, 2011) found positive correlations between various sleep parameters and physical activity (e.g., shorter sleep-onset latency, better sleep quality, fewer insomnia symptoms), there are also reports of null findings (Youngstedt et al., 2003). But how much exercise is healthy? There is no conclusive answer as yet; some studies found negative associations between high levels of activity and sleep (Driver and Taylor, 2000), whereas others found no such associations (Brand et al., 2009). There is evidence that fitness and not physical activity per se is associated with good sleep (Gerber et al., 2010). In summary, there does seem to be an association between sleep and physical activity, but the available results are not clear-cut.

Obesity

The link between sleep and obesity constitutes a wide field of research. During the last decades, not only has the worldwide prevalence of obesity doubled (Finucane et al., 2011) but sleep duration has reduced and poor sleep quality has become a frequent complaint. Sleep loss, especially, has been shown to result in increased hunger and appetite (Morselli et al., 2010). Epidemiological and experimental studies show that short sleep duration and poor sleep quality are risk factors for the development of obesity. In sum, most of the conducted studies found a significant association between short sleep (less than 5 or 6 h per night) and an increased obesity risk (e.g., Buxton and Marcelli, 2010), whereas an additional amount of sleep is correlated with lower BMI scores (Cappuccio and Miller, 2010). Those results are found not only in adults but also in younger age groups. Not only does the amount of sleep play an important role, obstructive apnea (OSA) is another very important issue. Studies show that the prevalence of obesity-related comorbidities such as OSA has increased up to more than 70% in women and 90% in men (Sareli et al., 2011).

In addition to these conditions, pain, heart disease, hypertension, cancer, and diabetes also affect sleep in terms of its duration, architecture, or quality – either as a direct consequence of the disease, or its medication or both.

Stress

Daily hassles and work stress have been shown to be associated with bad sleep and symptoms of insomnia (Hapke et al., 2013). Stress may lead to decreased sleep quality and, therefore, increase the risk for insomnia (e.g., Åkerstedt et al., 2012), with hyperarousal as a cognitive and physiological component playing a fundamental role (Pigeon and Perlis, 2006). Various studies report associations of higher presleep arousal in bad sleepers than in good sleepers (Morin, 2003). Furthermore, experimental studies found an effect of hyperarousal on sleep-onset latency (Wuyts et al., 2012).

Mental Disorders

Mental disorders, particularly depression and anxiety, are highly comorbid with sleep disturbances, as results of cross-sectional

studies show (e.g., Johnson et al., 2006). To date, the mechanisms underlying this comorbidity are still not fully understood. On the one hand, various studies show that individuals with sleep disturbances, especially insomnia symptoms, are more likely to develop future mental disorders (e.g., Wong et al., 2004). On the other hand, existing psychopathology, especially depression and anxiety, can increase the risk for development of adult insomnia (Skapinakis et al., 2013). In addition to anxiety and depression, aggression, delinquent behavior, attention-deficit hyperactivity disorder, and alcohol dependence are currently discussed as being associated with reduced sleep or sleep disturbances, such as insomnia or nightmares (Clinkinbeard et al. 2011; Cortese et al., 2006; Brower, 2003; Johnson and Breslau, 2001). It is still unknown if insomnia is predicted by early psychopathology.

Suicidal Tendency

Sleep is also connected with suicidal ideation, although the exact nature of their association has not been fully explored. Nevertheless, short sleep seems to play a role in risky and suicidal behavior in adolescents (Yen et al., 2010). In addition, insomnia symptoms and nightmares have been found to be associated with suicidal ideation. The duration of insomnia symptoms and nightmares, especially, seems to be significantly associated with suicide risk, independent of current sleep problems (Nadorff et al., 2013). In another study (Nadorff et al., 2012), 81 older adult patients above the age of 65 years were asked about their sleep, symptoms of depression, and suicidal ideation. In contrast to previous studies, insomnia symptoms, but not nightmares, were significantly related to suicidal ideation. This relation was mediated by depressive symptoms.

Environmental Factors

Various environmental factors have been found to impact sleep and decrease sleep quality. Blue light, especially, disturbs sleep, and therefore TV- and computer-time during the late evening should be reduced. In addition, noise negatively affects sleep. Ambient noise level, for example, is an external stimulus that is still processed by the sleepers' sensory functions, despite nonconscious perception of their presence. Exposure to noise varies between traffic, neighborhood noises, aircraft noises, and others. Research concerning environmental noise and sleep cover various fields, such as different situations and environments (at home, intensive care, etc.). Due to noise, sleep-onset latency can be prolonged, night awakenings might occur, and sleep architecture might be disturbed. The consequences of these sleep disruptions and disturbances are as broad as described above (Muzet, 2007).

Quality of Life

Various studies have shown that insufficient sleep is associated with a broad range of health impairments and overall impairment in quality of life. Chronic poor sleep quality, especially, is strongly associated with impaired quality of life. In detail, these impairments seem to be similar to chronic conditions, such as congestive heart failure and major depressive disorder (Philip et al., 2006). This association seems to be stable over time. During pregnancy, sleep problems seem to be the most important factor for reduced quality of life (Da Costa et al., 2009), whereas the successful treatment of sleep disturbances leads to improved quality of life (Sasai et al., 2010).

As seen above, sleep-related problems affect all areas of life, including cognitive development and performance, emotional well-being, work and physical activities, suicidal tendencies, and general physical and mental well-being. However, one has to bear in mind that most of the evidence available is based on cross-sectional and not longitudinal data. In addition, we need to know if increasing sleep duration in the long term has a positive impact on health.

In summary, sleep seems to have a broad range of associations with health. Assessment of sleep should therefore be an important component of general medical and psychological care. Moreover, assessment of sleep in children, adolescents, and adults as well as in the elderly may provide a better understanding of the prevalence of impaired sleep and its diverse implications on these populations in daily functioning.

Abstract

It is now widely recognized that sleep plays a pivotal role in the regulation of cognitive functions, especially considering learning and memory processes. In this article, we review key findings and evidences regarding the hypothesis that sleep exerts a promoting effect on plastic processes subtending memory consolidation. Nowadays, experimental findings show that recently learned information not only continues being processed but also can be modulated during sleep, that novel associations can be created during sleep and that emotion plays a modulatory role in sleep-dependent memory consolidation processes.

Introduction

A quarter to a third of human life is spent sleeping, suggesting the utmost importance of this particular state of vigilance. Notwithstanding the empiric recognition of its importance for our welfare, the functions of sleep have long remained poorly understood. Even nowadays it remains a matter of debate. Amongst other nonexclusive functions, growing evidence suggests that sleep participates in brain plasticity and memory consolidation processes (Maquet et al., 2003). Already in 1924, Jenkins and Dallenbach noticed less forgetting for novel verbal information when learning was followed by a period of sleep than after the same amount of time spent awake. However, they ascribed this beneficial effect to a reduced amount of external interference during sleep time, hence a passive shielding contribution of sleep in the process of memory consolidation. Subsequent studies that will be discussed here fostered the stronger hypothesis that sleep actively participates in memory consolidation processes. In this article, we will review key findings and evidences regarding the so-called sleep for memory hypothesis, and highlight open and unsolved issues. Before dwelling into the topic of consolidation, however, sleep and memory concepts will be shortly defined.

Sleep and Memory: Definitions and Key Concepts

Not One, but Different Memories in the Long Term

Popular models of memory organization have conceptualized long-term memory as composed of several specialized subsystems. These systems can be characterized considering the specific features of the information to encode and/or the degree of consciousness needed to integrate or retrieve this information. In this framework, a common distinction is made between declarative and nondeclarative long-term memories.

Declarative memories are verbalizable and consciously available, i.e., the recipient of these memories is usually aware that the stored information exists and is being retrieved. Declarative memory itself encompasses episodic and semantic memory subsystems. Episodic memory stores self-experienced events and facts, and allows replacing memories in their original learning context (e.g., a vivid souvenir of our wedding party). It is mostly subtended by hippocampal activity. At variance, semantic memory refers to the general knowledge that we have about the world, but is usually not anymore associated with the original learning context (e.g., we know that a cow is herbivorous, but there is very little chance that we still remember exactly how and when we have learned this information). A more distributed medial temporal cortical network subtends semantic memory. Importantly, episodic and semantic memories are not fully segregated subsystems, as episodic memories may become semanticized over time or repetition (e.g., we may know having had a great pleasure eating jam at our grandmother's home as a child, but not having in memory a specific and vivid episode associated with this knowledge).

Conversely, nondeclarative memories are usually not easily verbalizable and can be reexpressed (but this is not mandatory) without conscious knowledge. Therefore, nondeclarative memories will be mostly expressed through performance in perceptive, motor, and/or cognitive tasks. Nondeclarative memory encompasses various forms subtended by partially distinct neuroanatomical pathways. Procedural memory is the memory for skills and habits, mostly supported by cortico-subcortical pathways linked to the striatum. Classical conditioning with creation of stimulus–stimulus or stimulus–response associations is associated with amygdala (emotional) and cerebellum (skeletal) responses. And finally, neocortical activity is associated with priming and perceptual learning.

Sleep Cycles and Alternating Sleep Phases

Likewise memory, sleep is not a unitary phenomenon, especially if considered from a neurophysiological perspective. In man, sleep is divided into two main alternating phases, namely nonrapid eye movement (NREM) followed by rapid eye movement (REM) sleep. Four to five 90-min cycles of NREM–REM alternation are usually observed during a normal night of sleep. NREM sleep is further divided into three stages reflecting the increasing depth of sleep: N1, N2, and N3. As compared to wakefulness, electroencephalographic (EEG) activity recorded at the scalp level starts slowing down in the N1 stage with a decrease in alpha rhythms (8–12 Hz) and appearance of theta rhythms (4–7 Hz). Theta rhythms persist throughout stage N2, which is characterized by the occurrence of phasic events

including k-complexes (single sharp waves of large amplitude in the EEG) and spindles (waxing and waning EEG oscillations having a duration of 0.5–3 s in the 12–16 Hz frequency range). Spindle activity presents low intraindividual but high interindividual variability. Stage N3 is also called slow wave sleep (SWS) due to the predominance of slow oscillating waves (0.5–4 Hz) of high amplitude reflecting the high synchrony of discharges over large neuronal populations. At variance during REM sleep, EEG activity is more similar to wakefulness (hence its other name: paradoxical sleep) with a higher-frequency desynchronized activity of low amplitude. Additionally, definite features of REM sleep are muscle atonia and bursts of REMs. The relative proportion of NREM and REM within a sleep cycle varies across a night of sleep due to the progressive dissipation of homeostatic sleep pressure (reflected in slow wave activity (SWA)) and the higher circadian propensity for REM sleep at the end of the night. Consequently, the first half of the night is proportionally richer in SWS–N3 whereas the second part of the night is richer in REM sleep, the N2 stage being present 50% of the time all over the night.

Mechanisms of Sleep-Dependent Memory Consolidation

Memory consolidation refers to the temporal process lasting from a few minutes to several years by which initially fragile memory traces undergo a series of transformations eventually leading to their strengthening into long-term memory stores. Memory consolidation and progressive modification of the acquired information are actually instances of brain plasticity, i.e., the capacity of the brain to adapt its function and structure over time within certain boundaries to accommodate novel experience. In this perspective, reorganization of cortical networks, disinhibition of neuronal assemblies, modification and remodeling of synaptic connections should be the reflections of the processes of memory formation and consolidation. In this respect, experimental evidence suggests that the neurophysiological conditions of sleep are favorable to the consolidation of novel memories and their durable inscription in long-term memory stores, with two main theoretical models.

According to the model of the hippocampal–neocortical dialogue (Buzsáki, 1996; Hasselmo, 1999), novel information is stored during wakefulness within the hippocampus associated with theta–gamma oscillations. Consolidation of hippocampal information takes place during SWS in association with sharp-wave ripple (SWR) activity. Slow oscillations alternating hyperpolarization and depolarization phases trigger the repeated reactivation of hippocampal information through the joint activation of thalamic spindles and hippocampal SWRs, eventually transferring the stored representations toward neocortical stores during the depolarization phase of the slow oscillation (Figure 1). In this framework, sleep spindles play an important role in memory consolidation. If this model was associated with SWS and declarative memory, a less specific variant called the neuronal replay hypothesis proposes that cortical or subcortical activation patterns associated with a novel learning are reactivated during subsequent sleep stages (either NREM or REM stages), eventually leading to the replay of the learned information and its gradual integration and/or transfer into long-term memory stores.

The other main model is the synaptic homeostasis theory proposing that memory consolidation is a local use-dependent synaptic downscaling phenomenon that takes place during sleep as a secondary consequence of the growth of synaptic connections associated with novel learning at wake (Tononi and Cirelli, 2006). During wakefulness, the creation of novel memory traces is associated with locally increased synaptic potentiation and elevated energy and space costs, eventually leading to the saturation of the learning-related neuronal network. In this framework, homeostatically regulated slow oscillations during SWS would offer optimal conditions to downscale synaptic strength to their baseline level, thus restoring synaptic plasticity, while preserving the necessary differentiation between learning-related potentiated and other nonpotentiated synapses. Hence slow oscillations would refine the synaptic weight and indirectly improve the signal-to-noise ratio in learning-related neuronal ensembles (Figure 2).

Figure 1 Hippocampo–neocortical dialogue. Hippocampo–neocortical interactions during SWS are under the control of top-down slow cortical oscillations. Depolarization phases in the slow waves coordinate the repeated reactivation of the representation stored in the hippocampus together with SWR and sleep spindles, leading to the formation of 'spindles-ripples' events eventually leading to the transfer of the learned information into neocortical stores. Reprinted with permission from Born, J., Wilhelm, I., 2012. System consolidation of memory during sleep. Psychological Research 76, 192–203.

Figure 2 Synaptic Homeostasis Theory. During wakefulness, elevated noradrenaline levels and desynchronized neuronal activity favor information storage. Learning induces synaptic potentiation, reinforcing certain synapses, and creating new ones, a process that costs energy and space and eventually saturates the ability to learn new information. During NREM sleep, homeostatically regulated slow wave oscillations and low noradrenaline levels prevent further potentiation processes. The repeated alternation of depolarization and hyperpolarization phases in slow oscillations progressively downscales synaptic weights until baseline level while keeping the traces of previous experiences. Sleep Stages and Memory Systems: A Complex Interaction

Marked neurophysiological differences between sleep stages coupled with the existence of distinct systems in long-term memory entails that interactions are necessarily complex between sleep and memory processes. Accordingly none of the models described above can satisfactorily explain all of reported results in the field, and the search for a single, unitary model of sleep-dependent memory consolidation is not yet and may never be achieved. One possible approach to conceptualize these complex interactions is to consider that NREM and REM sleep entertain privileged relationships with distinct memory systems. In this respect, the dual-process hypothesis postulates that SWS supports the consolidation of declarative and spatial memories whereas REM sleep facilitates the consolidation of procedural memories. Alternatively, the sequential hypothesis proposes that memory consolidation occurs through sequential processes taking place during NREM and then REM sleep. An instance of this theory proposes that the recently learned information is made more resistant to interference during NREM sleep then consolidated and integrated into preexisting knowledge in long-term memory stores during REM sleep.

Arguments in favor of the dual-process hypothesis are provided by studies having compared the effect of postlearning sleep in the first part of the night (SWS predominance) with the effect of postlearning sleep in the second part of the night (REM sleep predominance). These studies evidenced a sleep-dependent retention of declarative spatial and verbal memories after early but not after late sleep. Conversely, sleep-dependent effects on priming and procedural learning were found after late but not after early sleep. On the other hand, sleep fragmentation preserving the overall structure and proportion of sleep stages deteriorates sleep-dependent consolidation processes, in line with the sequential hypothesis. Notwithstanding, other studies have reported outcomes that are difficult to integrate in these models. For instance, nondeclarative visual perceptual and motor tasks have been found to benefit from posttraining SWS and to be associated with spindles activity, whereas consolidation of declarative memories may benefit from posttraining REM sleep especially when the material comprises an emotional dimension. Hence it suggests that besides memory systems, the contribution of particular sleep stages in consolidation processes is also contingent upon the specific features of the material to be consolidated. Notwithstanding these reservations, we will present in separate sections the studies having investigated sleep-dependent consolidation for declarative and non-declarative memory for the sake of legibility and organization of the reading material.

From a methodological standpoint, the relationships between sleep and memory consolidation processes have been investigated using three main approaches (Peigneux et al., 2001; Rauchs et al., 2005). The first and most widely used paradigm is sleep deprivation (vs regular sleep) under the assumption that preventing sleep after learning should have a deleterious impact on memory consolidation processes and/or the underlying neural activity during memory retrieval. Sleep deprivation can be complete (whole night deprivation) or partial if a specific stage of sleep is under scrutiny. Partial sleep deprivation can be conducted by

awakening the participant at each occurrence of the targeted sleep stage (e.g., REM sleep) or using the first vs second half of the night (i.e., early vs late sleep) technique described above. The recall session task then takes place on the next day or later on after recovery of the sleep debt, and memory performance is compared between sleep and sleep-deprived conditions. The second line of research aimed at assessing how learning impacts on neural activity patterns during post-learning sleep, based on the assumption that learning-dependent changes in neurophysiological sleep patterns should reflect ongoing memory consolidation processes. Finally, paradigms using within-sleep stimulations have gained popularity in the recent years. Here, the impact of within-sleep stimulations at nonawakening thresholds was investigated, either during postlearning sleep to modify sleep patterns and boost overnight memory performance or to create novel memories during a sleep episode.

Sleep and the Consolidation of Declarative Memories

Interactions between sleep and declarative memory systems have been classically probed using hippocampus-dependent memory tasks such as learning of sentences, word pairs, object locations, faces, or spatial navigation. Early research using partial sleep deprivation suggests that retention of declarative material (e.g., word pairs) benefit more from sleep in the first half of night (i.e., richer in SWS) than from sleep in the second half of night (i.e., richer in REM sleep), a finding consistently replicated in subsequent studies (Diekelmann et al., 2009). Functional neuroimaging studies also show that sleep-dependent consolidation of declarative memories is accompanied by a functional reorganization in underlying brain activity at retrieval. For instance, delayed retrieval of learned word pairs or pictures is associated with increased hippocampal activity hours to a few days after the postlearning sleep (vs wakefulness) episode, a differential activity that dissipates over 3–6 months to be replaced by increased retrieval-related activity in medial prefrontal areas in participants having slept after the learning episode. Additionally, other functional magnetic resonance imaging (fMRI) studies using spatial navigation tasks showed that even in the absence of observable changes at the behavioral level, sleep after learning eventually promotes a shift from hippocampus- to striatum-based brain activity subtending the retrieval of these spatial memories, suggesting a sleep-dependent evolution toward less costly and more automated striatum-based navigation strategies (Orban et al., 2006).

Buzsáki's (1996) hypothesis of the hippocampo–cortical dialogue during sleep assumed that the progressive transfer of declarative memory-related activity from hippocampal to neocortical areas mostly takes place during NREM sleep. Accordingly, several animal studies (Poe et al., 2010) showed that neurons firing when exploring a new spatial environment are reactivated in the same temporal order (although not always at the same rate) during subsequent NREM sleep. Others also reported learning-related activations during REM sleep. Similarly, reactivation of learning-related hippocampal activity during SWS associated with increased memory consolidation was found in humans both for spatial (Peigneux et al., 2004) and verbal material. Taken together, these results suggest an association between neuronal reactivation during SWS and the offline consolidation of declarative memories.

The acquisition and sleep-dependent consolidation of semantic memories has received less attention than episodic memory consolidation, which may be linked to some extent to the difficulty segregating novel semantic memories from their episodic learning component. Notwithstanding, studies found associations between the acquisition of novel semantic material (e.g., a six-weeks French immersion course or Morse language learning) and increased REM sleep parameters, as well as associations between REM sleep inertia and semantic priming effects in narcoleptic patients. Besides, preserved detection of semantic discordance is possible during various sleep stages (Perrin, 2004). On the other hand, sleep deprivation studies having investigated the sleep-dependent processing of false memories upon the learning of lists of semantically related words have reported contradictory results both suggesting that sleep may favor cognitive abstraction processes typical of semantization, but also that these effects are largely contingent upon the quality of the encoding processes during learning (Lewis and Durrant, 2011). Noticeably, a main caveat in studies focused on the sleep-dependent processing of novel semantic information is that the time elapsed between learning and retrieval phases might be too short to evidence consistent effects, considering that the transfer of information from hippocampus-dependent episodic memory stores to neocortical semantic memory representations is a slow and gradual process that can take months or years to be achieved.

Sleep and the Consolidation of Nondeclarative Memories

The relationships between sleep and consolidation of nondeclarative memories have been mostly assessed using simple perceptual, motor, and visuomotor learning paradigms (Peigneux and Smith, 2010).

At the perceptual level, a prominent role of sleep in the consolidation of visual discrimination abilities has been repeatedly demonstrated. Although initial findings highlighted a predominant role of REM sleep, subsequent studies emphasized a main role of stage 2 sleep (N2) and SWS in posttraining consolidation, those views being reconciled by the demonstration that improvement to the task is associated with both SWS in the first sleep cycle and REM in the last sleep cycle of the night. Complementary studies also showed that repeated practice sessions within a same day actually deteriorate discrimination performance, suggesting neuronal saturation in primary visual cortex projection areas, unless a sleep episode (nap) is allowed. Furthermore, these naps studies found that a 30-min nap stops performance deterioration whereas a 60-min nap brings performance back to its original level and a 90-min nap leads to a performance improvement. As short naps usually only comprise NREM sleep periods and REM sleep can be additionally present in longer naps only, it further supports the hypothesis of a complementary role of sleep stages in the consolidation of visual discrimination abilities, partially in line with the sequential hypothesis. However, sleep-dependent improvements in performance are not consistently present in all perceptual modalities. For instance, whereas

several studies suggested an improvement in auditory discrimination abilities after sleep, others found equivalent performance after a period of wake.

The finger-to-thumb opposition and its keyboard equivalent the finger-tapping task have been widely used to study sleep-dependent motor learning. In these tasks, participants have to repeat as fast and accurately as possible a known, simple sequence of five finger movements. Most studies found a stabilization of performance over offline periods of wakefulness, whereas it increased after postlearning sleep, suggesting a consolidating role of sleep for learned motor representations. Postlearning sleep spindles activity was mostly found to be modified after learning, and to be correlated with performance improvement in these studies. Also, performance $\pm$ 30 min after the end of learning, but not later on during the day, is significantly increased and predictive of the next day's amplitude of improvement, suggesting the functional relevance of early transient phenomena of motor plasticity for sleep-dependent consolidation processes (Hotermans et al., 2006). Posttraining sleep changes have been also associated with more complex forms of motor learning, e.g., trampolining and dancing, or more recently three-ball cascade juggling, again leading to increased posttraining sleep spindle activity. In the motor tasks discussed above, an element to consider is the fact the learner is well aware that he is learning a new motor sequence or skill. Hence learning is relatively explicit, even if verbalizing is less helpful than repeated practice to improve motor performance. Additionally, presence of interactions between hippocampal and striatal activity during learning in a closely similar oculomotor paradigm was associated with subsequent sleep-related improvement in performance, suggesting that tasks in which the hippocampus is involved may to some extent benefit from NREM (stage 2) sleep consolidation processes. This interpretation is consistent with neuroimaging studies having shown the reactivation of learning-related activity and consolidation during posttraining REM sleep after learning higher order perceptual-motor cognitive skills in a probabilistic sequence learning task (i.e., a paradigm of implicit sequence learning) (Maquet et al., 2000). These data support the hypothesis that REM sleep is involved in the reprocessing and optimization of the high-order information contained in the material to be learned, as opposed to its motor component alone. Notwithstanding, other studies using sequence learning tasks have raised several issue. Indeed, some authors found using simpler sequential regularities that sleep is beneficial for sequence learning only when acquisition is explicit, with time alone being sufficient for the consolidation of implicitly acquired sequences. Since studies claiming a sleep-dependency exclusively for explicit sequential material have used deterministic, repeated sequences, and REM sleep-related reactivation studies have used much complex and abstract probabilistic sequences, it is possible that sleep (and especially REM sleep) mostly supports the consolidation of implicitly acquired complex relationship.

Besides sequence learning, other forms of procedural learning have been investigated. In the pursuit rotor task, participants use a cursor or the computer's mouse to track a pseudorandomly moving target (with hidden regularities). Performance to the task deteriorates both after total and late (i.e., filled with REM and N2 sleep) sleep deprivation but not after selective deprivation of REM sleep. Since performance improvement in the task is also associated with posttraining spindle activity, it suggests that offline consolidation is mostly subtended by stage 2 (N2) sleep. However, the initial skill level of participants at learning also determines which stage of sleep is modified after learning, as it has been shown that highly skilled participants present an increase in stage 2 spindles density after learning, which is correlated to performance at retest one week later, whereas performance of less skilled participants is related to changes in REM sleep density. At variance, performance on mirror-tracing tasks is better after late than early sleep and associated with increased REM sleep, but sleep stage 2 fast spindles activity (13–15 Hz) also correlates with skill improvement in this task. Altogether, these results suggest that postlearning modifications of sleep architecture are also contingent upon the skill levels achieved by participants at the end of learning, and that both stage 2 and REM sleep stages contribute to the consolidation of motor skills. Additionally, all motor tasks do not benefit to the same extent from posttraining sleep than motor sequence-based tasks do. Indeed, whereas a sleep-dependent improvement in performance, correlated with increased SWA, was observed using a rotation adaptation task in which subjects learned to adapt a reaching movement to imposed deviations (Huber et al., 2004), other studies merely found time- but not sleep-dependent offline changes in performance using the same task. On the whole, currently available studies indicate that the contributing role of sleep in the offline consolidation of motor abilities may be contingent upon several factors, including the stage of memory formation being considered, the degree of consciousness involved, and the parameters of the task.

Tickling Memories: The Contribution of Within-Sleep Stimulations

Within-sleep stimulation paradigms have been increasingly popular in the last decade. Indeed, this approach has proven particularly well suited to investigate current hypotheses about the neurophysiological mechanisms subtending memory consolidation processes. As stated above, consolidation of declarative, hippocampal-dependent memories has been mostly associated with NREM sleep. In this respect, it is assumed that slow oscillations in the delta frequency range (0.5–4 Hz) trigger the neurophysiological events allowing the transfer and integration of information in long-term memory stores. To test this hypothesis, transcranial Direct Current Stimulation (tDCS) that allows modifying neuronal excitability has been applied at the frequency of slow oscillations (0.75 Hz) during NREM sleep after learning. Results show increased retention of word pairs when tDCS was applied during sleep than after a normal night of sleep, whereas consolidation of a mirror-tracing (procedural memory) task was not affected by tDCS (Marshall et al., 2006). tDCS at other frequencies was not effective, suggesting the specificity of slow oscillations for memory consolidation of declarative memories. Using another approach, it was found that nonawakening presentation during SWS of an odor associated with the material to be

learned (i.e., card pairs in the game 'Memory') actually enhances retrieval performance on the next day, as compared to a normal, undisturbed night of sleep. Again, performance on a procedural memory task (i.e., the finger-tapping task) is not improved in such conditions. Additionally, fMRI recordings showed that odor cuing during SWS after learning triggers a hippocampal response associated with performance improvement in the declarative memory task. A complementary study using a nap paradigm demonstrated that postlearning odor cuing during a 40-min nap actually enhances memories to the level achieved over an undisturbed 90-min nap, whereas an undisturbed 40-min nap was not sufficient to enhance memory performance. Similar results have been obtained using auditory cues rather than odors during postlearning SWS in the context of an object location task, indicating the robustness of the observed effects. Finally in another study, participants learned to produce two melodies in time with moving visual symbols. Only one of the two melodies was then presented during the postlearning nap. Results showed higher performance for the melody represented during sleep than for the other one, suggesting that learning-related auditory stimulation during sleep can effectively and selectively trigger memory consolidation processes. An unsolved question is whether within-sleep stimulations could be used and beneficial in pathological or rehabilitation conditions, especially when considering emotional material.

Another open issue is whether the learning of novel information during sleep is possible. Although the topic was explored already a long time ago under the term of 'hypnopedia,' the few reported results have been far from convincing especially in man. On the other hand, successful conditioning of physiological responses during sleep has been reported in animals (Hennevin et al., 2007). Also, it is established that external stimulations continue to be processed during sleep at various levels of complexity. For instance, auditory event-related potentials are elicited after hearing one's own name both during wake and sleep, and evoked responses upon semantically deviant items are observed in all stages of sleep (Perrin, 2004). Hence many studies demonstrated the ability to process external stimulation while asleep, but failed to demonstrate the learning of new information during sleep. In a recent partial-reinforcement trace conditioning study, however (Arzi et al., 2012), participants were presented pleasant and unpleasant odors associated with two different tones during SWS and REM sleep, while monitoring the automatic sniff volume response. Results show that subsequent presentation of the tones alone during sleep, without the corresponding odors, induced a weak or a strong sniff volume of the response depending on the pleasantness of the odor previously associated with the tones, suggesting that participants successfully learned the odor–tone associations during sleep. Furthermore, conditioning was transferred during wakefulness (but only for stimuli conditioned during NREM sleep), even though the participants were not aware of the association. Although these results are stimulating, it remains to be tested whether the learning of more complex forms such as stimulus–stimulus association is possible during human sleep.

Emotion: A Modulating Factor in Sleep-Dependent Memory Consolidation

In everyday life, learning new information, facts, and events is often embedded within an emotional context. Each of us possesses a series of reminiscing states of mind and emotions associated with a relatively precise recollection of specific events, from the first steps of one's own child to the discovery of the World Trade Center tragedy. Emotion is a peculiar component of episodic memory involving additional neuroanatomical components (e.g., the amygdala complex) that are also activated during REM sleep. In this respect, the sleep-dependent processes subtending the consolidation of emotional memory have received increasing attention. The relationships between sleep and emotion-related memories have been assessed using intrinsically emotional material such as texts, word pairs, pictures, faces, or scenes, alternatively using neutral material associated with an emotional background.

There is a known advantage in the recall of emotional vs neutral material at wake. During postlearning sleep, late (REM-dominant) but not early (SWS-dominant) sleep also benefits more to the retention of emotional than of neutral texts, even when retested up to 4 years later. Conversely, the retrieval of emotional material is disrupted after a night of sleep deprivation. Central and peripheral components of an emotionally negative visual scene are not affected to the same extent by sleep deprivation, suggesting that the relevance of the emotional information to be processed is a selection factor in sleep-dependent consolidation processes. Indeed, whereas memory deteriorates for both components over a wakefulness period, only memory for central, relevant objects is preserved after a same period of time spent sleeping. However, post-training REM sleep may also play a role in protecting emotional memories against a overconsolidation or overboosting effect that would make these too invasive (as it is the case in post-traumatic disorders). Indeed, pharmacological blockade of the strong cortisol release during late (REM) sleep impairs consolidation of neutral but not of emotional texts, and even enhances recall performance for the latter. Hence it suggests that the natural and strong cortisol rise during REM sleep participates in hippocampus-dependent declarative memory consolidation for neutral material, but also protects from an overboosting in the consolidation of amygdala-dependent associations for emotional memories (Wagner et al., 2005).

Recollection of, and familiarity with, a stimulus reflect two different processes in memory. Whereas the former process involves the conscious retrieval of memories in an episodic context, the latter is an implicit expression of a memory trace that is not specifically linked to its context of acquisition. Whether sleep affects differentially or to the same extent recollection and familiarity processes for emotional material is debated. For instance, whereas Hu et al. (2006) observed sleep-related improvements both in response familiarity and recollection measures, others found that such improvement is limited to one of the two processes only. Furthermore, others found that sleep does not affect either dimension of memory at the behavioral level, in line with the hypothesis that emotional memories are of such ecological relevance that their consolidation should take place during posttraining wakefulness already. Besides equal performance at the behavioral level

however, brain imaging data also disclosed stronger connections between the hippocampus and the medial prefrontal cortex during the recollection of emotional material when participants were allowed to sleep after learning, whereas recollection was associated with higher activity in amygdala and occipital areas after sleep deprivation (Sterpenich et al., 2007), suggesting that sleep contributes depotentiating emotional reactivity and integrating memory core information into neocortical networks subtending long-term memory.

According to the sleep to forget and sleep to remember hypothesis (Van der Helm and Walker, 2009), the specific patterns of neurophysiological activity during sleep (and especially during REM sleep) would facilitate the decoupling of declarative memories from their emotional context. In this respect, it is assumed that the high concentration of aminergic neurotransmitters and the increased amygdala activity during wakefulness promote the encoding of emotional memories with their affective context. During subsequent REM sleep, the dramatic rise of cholinergic activity associated with theta oscillations would participate in the reactivation of the novel information, consolidating emotional memories. However, the concurrent decrease in aminergic activity during REM sleep would also lead to a depotentiation of the emotional tone initially associated with the learned information. Supporting this hypothesis, we showed that sleep reduces the facilitating effect of emotional congruency in the background mood context during the learning and retrieval phases, hence suggesting that postlearning sleep effectively releases recently learned memories from their emotional context (Deliens et al., 2012). At variance however, other studies confirmed a role for REM sleep in the processing of emotional memories, but suggested that the affective tone is preserved rather than reduced after posttraining sleep. An important difference between these studies is that an irrelevant emotional context surrounding neutral information was suppressed in the former case, whereas the consolidated information after sleep was intrinsically emotional in the latter case. Hence, sleep may indeed promote the decoupling between recently learned information and its emotional envelope, but only when this emotional information is not or weakly relevant.

Although findings are still inconsistent and the need for further research is warranted, studying the role played by sleep in emotional decontextualization processes is a particularly fascinating area of research considering the prevalence of psychiatric disorders involving mood disturbances that are associated with sleep disorders. For instance, the posttraumatic stress syndrome is specifically associated with REM sleep disturbances. Hence, a better understanding of the REM sleep mechanisms involved in emotion processing could benefit to the possible treatment of such pathologies.

Sleep Disorders across the Life Span

© 2015 Elsevier Ltd. All rights reserved.

Abstract

It is estimated that 10% of the population suffer from sleep disorders, which have profound and widespread effects on human health. Although the diagnosis and treatment of sleep disorders is a relatively young discipline, understanding of the diagnosis, pathophysiology, and treatment of sleep disorders is evolving at a rapid pace. There are around 90 distinct sleep disorders in resent research; most are marked by one of these symptoms: excessive daytime sleepiness, difficulty initiating or maintaining sleep, and abnormal events occurring during sleep. The sleep disorders are associated with increased risk of hypertension, diabetes, obesity, coronary heart disease, heart attack, stroke, and depression. This article focuses on incorporating the essential features of common sleep disorders across the life span.

Sleep is a universal phenomenon that occupies almost one-third of human lifetime (Lee-Chiong, 2004). Sleep influences most physiologic processes in the body, and is, in turn, affected by specific circadian, medical, neuropsychiatric, and behavioral disorders, the sleep environment itself, and medication usage (Lee-Chiong, 2004).

Sleep disorders are common, and at least 10% of the population suffer from a sleep disorder that is clinically significant and of health importance (Ram et al., 2010). Although the diagnosis and treatment of sleep disorders is a relatively young discipline in medicine and psychopathology dating to the late 1970s, understanding of the diagnosis, pathophysiology, and treatment of sleep disorders is evolving at a rapid pace (Roehrs and Roth, 2004). At present, nearly 90 different sleep disorders are listed in the International Classification of Sleep Disorders (ICSD, Ed 2), which can be divided into eight categories (American Academy of Sleep Medicine, 2005). Sleep disorders vary widely in their complexity, their comorbidities, the risks they represent, and the scope of their manifestations (Colten and Altevogt, 2006). The four major sleep complaints include excessive daytime sleepiness; insomnia; abnormal movements, behaviors, or sensation during sleep; and inability to sleep at the desired time (American Academy of Sleep Medicine, 2005).

In addition, sleep problems are associated with health problems, functioning and well-being, work-related indicators, and health care expenditures (Roth et al., 2002). A number of recent studies have demonstrated that individuals with current sleep problems report significantly poorer health, less energy, and worse cognitive functioning than those categorized as having no sleep problem (Roth et al., 2002). The long-term effects of sleep loss and sleep disorders have been associated with a wide range of deleterious health consequences including increased risk of hypertension, diabetes, obesity, coronary heart disease, heart attack, heart failure, stroke, and depression (Colten and Altevogt, 2006).

The principles of sleep disorder treatment include first to find the cause of the sleep disturbance and vigorously treat the primary or comorbid conditions causing the sleep disturbance. If the treatment does not resolve the problem, then treatment should be directed at a specific sleep disturbance that may be caused by various neurological and medical diseases (Chokroverty, 2010).

Sleep Patterns Change across the Life Span

Sleep architecture changes continuously and considerably with age. From infancy to adulthood, there are marked changes in how sleep is initiated and maintained, the percentage of time spent in each stage of sleep, and overall sleep efficiency. Sleep requirements change dramatically from infancy to old age. A general trend is that sleep efficiency declines with age (**Table 1**) (Chokroverty, 2010; Colten and Altevogt, 2006). Such changes will be significantly affected by neurological, environmental, and genetic factors as well as comorbid medical or neurological disorders.

Common Sleep Disorders in Children

The diagnoses of sleep disorders are often overlooked and underdiagnosed in the pediatric population (Faruqui et al., 2011). Sleep problems in preadolescents have been reported for 10–33% of the population (Fricke-Oerkerman et al., 2007; Ipsiroglu et al., 2002; Meijer et al., 2000). An estimated 40% of adolescents report experiencing some forms of sleep problems, including issues of sleep difficulty, snoring, and sleep apnea (Corbo et al., 2001; Gozal and Pope, 2001; Tarasiu et al., 2007).

Sleep disorders in children can be divided into five categories, which are composed of difficulty falling asleep, difficulties with arousal, sleep-related movement disorders, sleep-related breathing disorder, and excessive daytime sleepiness (Carno et al., 2003). Many disorders are included in these categories. There are characteristic symptoms and ages of onset for the different sleep disorders.

Difficulty Falling Asleep

Difficulty falling asleep related to the process of going to sleep is called insomnia. Insomnia among children is often reported

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21027-1

Table 1 Sleep patterns change across the life span

Age group	*Average sleep duration*	*Sleep feature*
Newborns	15–16 h per day	1. Biphasic 2. By 3 months of age, the non-REM (NREM)/REM cycling pattern of adult sleep is established 3. REM sleep constitutes 50% of total sleep time during early infancy 4. Ultradian sleep cycles of REM and NREM sleep states are substantially shorter for infants (50–60 min) 5. Some degree of nighttime waking is normal in young children, particularly during early infancy, when circadian mechanisms are still immature and nighttime feedings a necessity for most infants until about 6 months of age
Child	11 h per day	1. Biphasic 2. REM sleep declining by age 5 years to 20%
Adolescent	9–10 h per day	Monophasic
Adults	7.5–8 h per night	1. Monophasic 2. Ultradian sleep cycles of REM and NREM sleep states are substantially longer for adults (90–100 min)
Elderly people	7 h per night	1. Biphasic 2. Progressive decrease in slow wave sleep (SWS) and REM 3. Earlier bedtimes and wake times 4. Sleep efficiency continues to decline with age

by caretakers and characterized by bedtime resistance, an inability to sleep independently, or both (Colten and Altevogt, 2006). It can manifest as bedtime resistance, in which a child may cry, repeatedly attempt to leave the room/bed, or engage in other behaviors intended to forestall sleep onset. Delayed sleep onset and issues of sleep anxiety are also common, such as needing a parent in the room to fall asleep, the child signals being afraid to sleep alone and/or to sleep in the dark. In school-aged children, this can be a significant problem and may lead to poor school performance (Colten and Altevogt, 2006; Owens et al., 2000).

Children who lack structured bedtime routines or have irregular sleep habits represent a high-risk population. Other influences that may impede settling at bedtime include temperamental characteristics, anxiety, acute illness, medication side effects, and coexisting medical conditions such as attention deficit hyperactivity disorder (ADHD), autism, and other developmental disabilities (Hoban, 2010). Behavioral interventions and establishing good 'sleep hygiene' are the preferred method and goal of treatment (Carno et al., 2003; Hoban, 2010). Use of a structured, age-appropriate bedtime routine helps children sleep.

In addition, night waking is considered problematic when it is excessively prolonged or frequent for age, or when it is excessively disruptive to other members of the household (Hoban, 2010). Overall, about 20% of children below age 2 years exhibit night waking inducing concern by parents (Hoban, 2010). A variety of predisposing influences may be associated with problematic night waking, some of which relate to expected developmental changes during early childhood. Separation anxiety and cosleeping with a parent are associated with increased risk of arousal and awakening during nighttime sleep (Hoban, 2010; Kryger et al., 2005).

Another strong influence of sleep disorder on older school-age children is the well-recognized tendency toward delayed sleep phase type that develops near adolescence, with a reported prevalence of 7–16% (Reid et al., 2004). Delayed sleep phase syndrome (DSPS), one kind of circadian rhythm sleep disorder, may be diagnosed when this tendency results in difficulty maintaining school schedule, as well as chronic or recurrent inability of the child to fall asleep and wake up at conventional and socially acceptable times (American Academy of Sleep Medicine, 2005; Anstead, 2000; Carno et al., 2003; Reid et al., 2004). Besides a result of alterations of circadian timing, there is recent evidence that alterations in the homeostatic regulation of sleep may play an important role in the pathophysiology of DSPS (Watanabe et al., 2003). As common in adolescents, habitually later bedtime and waking time on nonschool nights, end to perpetuate or worsen the tendency toward DSPS (Crowley et al., 2007). Treatment includes a gradual change in the child's sleep time until the desired sleep–wake time is achieved. Both the parents and the child must be committed to the prescribed plan for success (Carno et al., 2003).

Difficulties with Arousals

Parasomnias are episodic disturbances of sleep that happen most often in preschool and school-aged children (D'Cruz and Vaughn, 2001). These aberrant arousals are associated with a spectrum of abnormal behavior or physiologic events that occur in association with sleep, specific sleep stages, or sleep–wake transitions and can include night terrors, sleepwalking, sleep talking, and so on (D'Cruz and Vaughn, 2001; Hoban, 2010). During a parasomnia episode, children are difficult to awaken during the event, and if awakened, demonstrate little or no recall for the episode (D'Cruz and Vaughn, 2001). Multiple parasomnias often occur in the same person at different ages. They are more common in boys than in girls, and often found in conjunction with a positive family history (D'Cruz and Vaughn, 2001; Hublin et al., 2001; Lecendreux et al., 2003; Owens et al., 2000). Limited evidence suggests that obstructive sleep apnea (OSA) or restless legs syndrome (RLS) may represent a treatable precipitant of these parasomnias for some children (Guilleminault et al., 2003). Studies have shown a relationship between the child's stress

level and parasomnias such as night terrors, somniloquy, and body rocking (Laberge et al., 2000).

Night terrors, sleepwalking, and confusional arousal in children are thought to represent forms of incomplete arousal from non-rapid eye movement (REM) sleep. Exacerbations of non-REM arousal parasomnias are often triggered by sleep deprivation or intercurrent illness. Night terrors and confusional arousal affect up to 17% of children (Laberge et al., 2000) but are most commonly observed in toddlers and preschoolers with no dream association or recollection of the incident. These incidents are accompanied by intense autonomic and motor symptoms, which range from moaning, quiet crying, sitting upright in bed, or screams to extreme agitation (Hoban, 2010; Laberge et al., 2000). Patients appear highly confused and fearful. Episodes can last from only seconds to as long as 1 h, but most typically remit within minutes (Carno et al., 2003; Hoban, 2010).

Sleepwalking and sleep talking are more common in school-age children. Sleep talking (somniloquy) is the most frequent parasomnia and can be considered a universal experience (Carno et al., 2003). Although 40% of children exhibit at least one episode of sleepwalking between the ages of 5 and 12 years, frequent sleepwalking affects only 2–3% with a peak prevalence near 10 years of age (Laberge et al., 2000). Episodes of sleepwalking consist of quiet ambulation lasting several minutes, which may include semipurposeful activities such as wandering to some place of the house or urinating in inappropriate locations (Hoban, 2010). Injuries and violent activities have been reported during sleepwalking episodes but generally individuals can negotiate their way around the room (Chokroverty, 2010).

Use of scheduled awakenings is often effective for the treatment of the non-REM arousal parasomnias in children whose sleepwalking or night terrors occur at predictable times of the night (Hoban, 2010). For sleepwalking, security of the environment is important. Drug treatment using clonazepam may be effective for children having particularly frequent or severe forms of sleepwalking and night terrors (Remulla et al., 2004).

Nightmares during childhood are common, and over half of early school-aged children were affected on an occasional basis but only 3% of children show this disturbance more than once a week (Smedje et al., 1999). Different from night terrors, nightmares arise from REM sleep and are thought to result from awakening during a frightening dream. The child awakens fully, and has recollection of the dream content. Persistent nightmares, which are unexpectedly frequent, prolonged, or violent in content, need especially further attention of potential psychological and medical causes (Hoban, 2010). It may be helpful to teach stress modification techniques based on age, which is also beneficial for sleep talking (Howard and Wong, 2001).

Sleep enuresis in children is defined as urinating more than twice a week for children older than 5 years and characterized by recurrent involuntary voiding during sleep at a level that is inappropriate for age (American Academy of Sleep Medicine, 2005). Nocturnal enuresis becomes less common with advanced age, affecting 15% of 3- to 10-year-olds, but only 2% of 13-year-olds (Laberge et al., 2000). It more commonly occurs in boys than in girls. Postulated causes of primary enuresis include immaturity of arousal mechanisms, reduced functional bladder capacity, and genetic predisposition. Children with frequent enuresis often respond to behaviorally based therapies and conditioning programs (Butler et al., 2007; Lottmann and Alova, 2007). Drug treatment like desmopressin (Ferrara et al., 2008) and imipramine (Neveus et al., 2008) is also effective, which is best used within the context of a comprehensive and closely supervised treatment program.

Sleep-Related Movement Disorders

RLS and periodic limb movement disorder (PLMD) are different but related conditions in children and are often comorbid conditions, but either of them may present independently. The RLS criteria in childhood include the adult criteria and additional criteria designed to address the absence or uncertainty of verbal reports (American Academy of Sleep Medicine, 2005). Some children with growing pains may actually have RLS as well (Rajaram et al., 2004). Leg restlessness and growing pains affect 17% and up to 8% of children, respectively (Chervin et al., 2002), but only 2% of children meet diagnostic criteria of RLS (Picchietti et al., 2007). Genetic influences and iron deficiency are suggested as the causes of RLS in the pediatric age group (Muhle et al., 2008; Oner et al., 2007). Childhood PLMD is characterized by excessive periodic limb movements occurring over five times per hour of sleep during polysomnography (PSG), accompanied by clinical complaints of disturbed sleep (American Academy of Sleep Medicine, 2005). The pathophysiology of PLMD is still unknown, but dopaminergic impairment has been implicated (American Academy of Sleep Medicine, 2005). Studies have reported possible association between childhood RLS/PLMD and symptoms of ADHD (Cortese et al., 2005). Treatment options for childhood RLS/PLMD include iron supplementation with low ferritin levels or iron deficiency (Picchietti et al., 2008), or judicious use of dopaminergic agonists (Walters et al., 2000).

Sleep-related rhythmic movement disorder (RMD) is characterized by recurrent and well-stereotyped rhythmic behaviors associated with sleep, which is sleep–wake transition parasomnias that involve rhythmic movement of a large muscle group (American Academy of Sleep Medicine, 2005; Hoban, 2003). Body rocking, head or body rolling, and head banging are some common examples. Episodes of rhythmic movement usually last for several minutes and may recur throughout the night (Hoban, 2010). Rhythmic movements may represent self-comforting or a sleep-inducing behavior (D'Cruz and Vaughn, 2001). Parents may be unaware of the sleep disturbance unless some sort of noise is involved. Sleep-related rhythmic behaviors are observed in a majority of infants, usually between 8 and 18 months, but disappear around 5 years of age in most children (Dyken and Rodnitzky, 1992). Only 3% of children manifest prominent rhythmic behaviors associated with sleep in early adolescence (Laberge et al., 2000). RMD is a self-limited condition that does not need treatment in most children. But for children exhibiting particularly prolonged

or violent forms of RMD, benzodiazepines, behavioral therapies, or use of padding are suggested (Hoban, 2010).

Sleep-Related Breathing Disorder

OSA refers to a breathing disorder during sleep that is characterized by either prolonged partial upper airway obstruction (hypopnea) and/or intermittent complete obstruction (apnea) (American Academy of Sleep Medicine, 2005). OSA in children may not present as overtly as in adults and sometimes associated sleep disturbance can be the most obvious symptom and the reason why the child comes to medical attention in the first place (Wiggs, 2003). The prevalence of OSA is approximately 2% in otherwise normal young children (American Academy of Sleep Medicine, 2005). Although OSA can occur in children of any age, it is most common at preschool ages around 2–8 years, a time coincident with tonsils and adenoids being largest relative to the underlying airway (Colten and Altevogt, 2006). Other genetic, neurological, and craniofacial conditions and obesity are associated with increased risk for the development of childhood OSA. The clinical features of OSA in children include snoring, unusual sleeping positions, headache, and daytime sleepiness (American Academy of Sleep Medicine, 2005). Children with OSA have an increased risk for neurocognitive deficits such as behavioral problems, poor learning, and/or ADHD, which result from the lower oxygen levels during the episodes of sleep apnea (Marcus, 2001). Adenotonsillectomy is the most common treatment of childhood OSA. Otherwise, nasal continuous positive airway pressure (CPAP) is an alternative first-line treatment for OSA in children of all ages (O'Donnell et al., 2006). Other treatments are then advised, such as weight loss, use of supplemental oxygen, positional therapy, or more extensive surgery (Hoban, 2010; Schechter, 2002).

Excessive Daytime Sleepiness

Narcolepsy is a neurologic disorder characterized by excessive daytime somnolence, which may be accompanied by cataplexy, sleep paralysis, and hallucinations at sleep onset or offset. It appears commonly during the second decade of life and after the reported onset of puberty (Kotagal, 1996). Onset of narcolepsy can also have a negative impact on school performance. Misdiagnosis of narcolepsy is common in children owing to similar psychiatric disorders and emotional and behavioral changes. Treatment of narcolepsy in children, in most respects, parallels that of adults (Hoban, 2010). However, large-scale clinical trials have not examined the efficacy and safety of drugs to treat narcolepsy in children and adolescents (Colten and Altevogt, 2006).

Bruxism (Tooth Grinding)

Bruxism often presents between ages 10 and 20 years, but it may persist throughout life, often leading to secondary problems such as temporomandibular joint dysfunction. It is also commonly noted in children with mental retardation or cerebral palsy. The episode is characterized by stereotypical tooth grinding and is precipitated by anxiety, stress, and dental disease (Hoban, 2010).

Common Sleep Disorders in Adults

Sleep disorders have an estimated prevalence of 15–27% in the adult population (Roth et al., 2002). While there are approximately 90 sleep disorders recognized by the medical community (American Academy of Sleep Medicine, 2005), the authors have put together a list of the most common sleep disorders seen in adults as follows. Many people have more than one sleep issue.

Insomnia

Insomnia is defined as a repeated difficulty with sleep initiation, duration, consolidation, or quality that occurs despite adequate time and opportunity for sleep and results in some form of daytime impairment (American Academy of Sleep Medicine, 2005). The prevalence in representative population surveys is 10–14% for chronic insomnia and 20–40% for occasional, or less severe, insomnia (Kryger et al., 2005). The precise causes of insomnia are poorly understood but, in general terms, involve a combination of biological, psychological, and social factors (Colten and Altevogt, 2006). Surveys consistently find that the prevalence of insomnia is higher in women and that it increases with age. In addition, insomnia is more prevalent in those with medical illness, substance users, and those with anxiety or depressive disorders (Roehrs and Roth, 2004; Kryger et al., 2005). Among adults, insomnia complaints typically include reported difficulties initiating or maintaining sleep. Concerns about extended periods of nocturnal wakefulness or insufficient amounts of nocturnal sleep usually accompany these complaints. Consequences of insomnia in adults include an increased likelihood of accidents and absenteeism, diminished performance, impaired judgment and social or vocational functioning, polydrug abuse (including alcoholism), increased use of health care resources, reduction in quality of life, and disturbance in interpersonal relationships. It is important and necessary that short-term sleep disturbance be promptly recognized and appropriately treated before learned habits, attitudes, and coping mechanisms incongruous with sleep become established and perpetuate the sleep disturbance. Insomnia is treatable with a variety of behavioral and pharmacological therapies, which may be used alone or in combination. Therapy has to address the predisposing, precipitating, and perpetuating factors of insomnia (Lee-Chiong, 2004).

Sleep-Disordered Breathing

Sleep-disordered breathing (SDB) refers to a spectrum of disorders that feature breathing pauses during sleep. The most common disorder is characterized by obstructive apneas and

hypopneas (Kryger et al., 2005). Obstructive sleep apnea syndrome (OSAS) is characterized by repetitive episodes of complete (apnea) or partial (hypopnea) upper airway obstruction occurring during sleep (American Academy of Sleep Medicine, 2005; Kryger et al., 2005). These events often result in loud snoring, blood oxygen saturations, and many and recurrent periods of arousal. They typically recur throughout the evening, at times reaching numbers substantial enough to produce sleep fragmentation and subsequent daytime sleepiness (American Academy of Sleep Medicine, 2005). The diagnosis of OSAS requires detection, by PSG, of at least five or more apneas or hypopneas per hour of sleep (Colten and Altevogt, 2006). OSAS tends to affect mainly middle-aged individuals and is strongly associated with obesity. An estimated 4% of men and 2% of women between the ages of 30 and 60 years in the United States have OSAS (Lee-Chiong, 2004). OSAS increases the risk for hypertension, coronary artery disease, heart failure, arrhythmias, cerebrovascular disease, stroke, glucose intolerance, diabetes, and even mortality (Colten and Altevogt, 2006; Lee-Chiong, 2004). In adults, OSA is most effectively treated with CPAP and weight loss (Kryger et al., 2005). Other options, although less effective, include a variety of dental appliances or surgery (e.g., uvulopalatopharyngoplasty) (Kryger et al., 2005).

Sleep-Related Movement Disorders

Restless Legs Syndrome

RLS is a sensorimotor disorder characterized by a strong, nearly irresistible urge to move the legs (American Academy of Sleep Medicine, 2005). It is also associated with paresthesias – uncomfortable feelings – which individuals describe as creeping, crawling, jittery, itchy, aching, or burning feelings. The symptoms are partially or completely relieved by movement. The urge to move and unpleasant sensations worsen during periods of rest or inactivity, especially in the evening and at night, causing most individuals difficulty falling sleep and maintaining sleep (American Academy of Sleep Medicine, 2005). At least 80–90% of RLS patients have periodic limb movement in sleep (PLMS) and may also have periodic limb movement in wakefulness; however, one-third of those with PLMD will have RLS (Chokroverty, 2010; Michaud et al., 2000). The prevalence has been reported at about 5–10% for adult populations but the prevalence of most severe cases is approximately 2.5%, which makes it one of the most common movement disorders and sleep disorders (Chokroverty, 2010; Colten and Altevogt, 2006). In most surveys, the prevalence is greater in women than in men and the disease is chronic and progressive (Chokroverty, 2010). Iron, dopamine, and genetics appear to be primary factors in the pathology of RLS (American Academy of Sleep Medicine, 2005). There are both behavioral and pharmacological treatments for RLS. Four classes of prescription medications are mostly used for the treatment of RLS: dopaminergic agents, benzodiazepines, opioids, or anticonvulsants, in which dopaminergic agents are the primary treatment option for RLS (Colten and Altevogt, 2006). Mild to moderate symptoms can be treated sometimes by lifestyle changes, including maintaining a normal sleeping pattern, taking supplements to manage iron deficiencies, and minimizing consumption of alcohol, caffeine, and tobacco (Colten and Altevogt, 2006).

Periodic Limb Movement Disorder

PLMD is defined as periodic episodes of repetitive, highly stereotyped limb movements characterized by rhythmic extensions of the big toe, dorsiflexions of the ankle, and occasional flexions of the knee and hip, which cannot be explained by any other sleep disorder. Nonetheless, these stereotypical jerks can partially arouse or awaken the individual, leading to sleep fragmentation and complaints of insomnia or hypersomnolence (American Academy of Sleep Medicine, 2005). It was found to have a population prevalence of 4% in studies of five European countries (Kryger et al., 2005). It is also observed in individuals with narcolepsy, rapid eye movement sleep behavior disorder (RBD), OSA, and hypersomnia (Chokroverty, 2010). PLMD is associated with high rates of depression, memory impairment, attention deficits, oppositional behaviors, and fatigue (American Academy of Sleep Medicine, 2005). Similar to RLS, dopaminergic medications are helpful in alleviating the disorder's symptoms.

Narcolepsy and Hypersomnia

Narcolepsy and idiopathic hypersomnia are characterized by a clinically significant complaint of excessive daytime sleepiness that is neither explained by a circadian sleep disorder, SDB, or sleep deprivation, nor caused by a medical condition disturbing sleep (American Academy of Sleep Medicine, 2005). Narcolepsy is characterized by narcoleptic sleep attacks (100%), cataplexy (60–70%), sleep paralysis (25–50%), hypnagogic hallucinations (20–40%), disturbed night sleep (70–80%), and automatic behavior (20–40%) (Chokroverty, 2010). In addition to the major manifestations, patients with narcolepsy may also have four important comorbid conditions: sleep apnea, PLMS, RBD, and nocturnal eating disorder (Chokroverty, 2010). Excessive sleepiness may manifest as pervasive drowsiness, frequent napping, and unexpected and overpowering sleep attacks. Repetitive awakenings, automatic or inappropriate behavior, and memory impairment are associated features. It is a lifelong condition but it generally is less severe and may even disappear in old age (Chokroverty, 2010; Lee-Chiong, 2004). It has a population prevalence of 0.03–0.16% of the general population (Lee-Chiong, 2004).

Excessive sleepiness in persons with idiopathic hypersomnia, which closely resembles narcolepsy syndrome, manifests as extended major sleep episodes (lasting over 8 h) and prolonged naps (up to 1–2 h) (Lee-Chiong, 2004). The sleep pattern, however, is different from that of narcolepsy. The patient generally sleeps for hours but the sleep is not refreshing. The patient does not give a history of cataplexy, snoring, or repeated awakenings throughout the night. Recurrent hypersomnia can manifest in two forms: hypersomnia only or accompanied by binge eating and hypersexuality (Kleine–Levin syndrome) (Colten and Altevogt, 2006; Lee-Chiong, 2004).

The diagnosis of narcolepsy and hypersomnia is based principally on the multiple sleep latency test, which objectively quantifies daytime sleepiness, or by measuring cerebrospinal fluid hypocretin-1 (Kryger et al., 2005). Secondary cases of narcolepsy or hypersomnia are also common, which can occur in the context of psychiatric disorders, central nervous system tumors, Parkinson's disease, multiple sclerosis, head trauma, and genetic disorders (Colten and Altevogt, 2006). Treatment for narcolepsy and hypersomnia is symptomatically based. In most cases, pharmacological treatment (such as modafinil or amphetamine-like stimulants) is needed. Behavioral measures are helpful but rarely sufficient (Colten and Altevogt, 2006).

Circadian Rhythm Sleep Disorders

Circadian rhythm sleep disorders arise from chronic alterations, disruptions, or misalignment of the circadian clock in relation to environmental cues and the terrestrial light–dark cycle (Colten and Altevogt, 2006). The ICSD 2 designated nine different circadian disorders, and the common primary disorders include delayed sleep phase type, advanced sleep phase type, irregular sleep–wake type, free-running type, shift work type, and jet lag type (American Academy of Sleep Medicine, 2005; Colten and Altevogt, 2006). These conditions often result in complaints of insomnia and excessive sleepiness. In addition to physiological and environmental factors, maladaptive behaviors influence the presentation and severity of the circadian rhythm sleep disorders (American Academy of Sleep Medicine, 2005). These disorders may be comorbid with other neurological or psychiatric disorders, making the diagnosis and treatment difficult (Kryger et al., 2005). Treatment for this disorder requires resynchronizing to a more appropriate phase to the 24-h light–dark cycle. In addition to a structured sleep–wake schedule and good sleep hygiene practices, potential therapies include resetting the circadian pacemaker with bright light, melatonin, or a combination of both (Colten and Altevogt, 2006; Reid et al., 2004).

Parasomnias

Parasomnias are undesirable physical, behavioral, or experiential phenomena that occur during entry into sleep, within sleep, or during arousals from sleep (American Academy of Sleep Medicine, 2005). Parasomnias generally manifest as central nervous system activation transmitted into skeletal muscles and the autonomic nervous system channels, often with experiential concomitants, and tend to occur during the transition from one state to another. Parasomnias encompass abnormal sleep-related movements, behaviors, emotions, perceptions, dreaming, and autonomic nervous system functioning, which may result in injuries, sleep disruption, adverse health effects, and psychosocial problems (American Academy of Sleep Medicine, 2005). The ICSD 2 lists 15 items and some of these entities are rare (American Academy of Sleep Medicine, 2005). The common primary sleep parasomnias include disorders of arousal (e.g., confusional arousals, sleepwalking, and sleep terror), RBD, nightmare disorder, sleep enuresis, sleep-related groaning, and eating disorder, most of which are usually common in children (see Section Common Sleep Disorders in Children) (Lee-Chiong, 2004).

Common Sleep Disorders in Older Adults

Sleep disturbances in older adults are often multifactorial. It has been estimated that approximately 50% of older adults complain about difficulty initiating or maintaining sleep (Crowley, 2011; Neikrug and Ancoli-Israel, 2010). However, this higher prevalence of sleep disruption is less a function of age and more a function of other factors that accompany aging, which include the increased presence of medical and psychosocial comorbidities, increased medication use, advances in the endogenous circadian clock, and a higher prevalence of specific sleep disorders (e.g., OSA, PLMS, and RLS) (Bloom et al., 2009). Of major clinical concern is the strong bidirectional relationship between sleep disorders and serious medical problems in older persons (Bloom et al., 2009). Individuals with sleep disorders negatively affect the outcomes of chronic diseases such as hypertension, depression, cardiovascular, and cerebrovascular disease and are associated with increasing mortality and morbidity. Conversely, individuals with any of these diseases are at higher than normal risk of developing sleep problems (Cuellar et al., 2007; Foley et al., 2004; Neikrug and Ancoli-Israel, 2010; Taylor et al., 2007). The most common primary sleep disorders in the elderly include insomnia, SDB, RLS/PLMS, and RBD (Crowley, 2011). Treatment of primary sleep problems can improve the quality of life and daytime functioning of older adults (Neikrug and Ancoli-Israel, 2010).

Insomnia

Numerous studies have shown that the prevalence of insomnia is higher in older adults than in younger adults, with estimates as high as approximately 40% in those aged over 65 years (Ancoli-Israel, 2009; Foley et al., 2004; Paudel et al., 2008). The consequences of insomnia in older adults are substantial and include daytime functional impairments, poor health, decreased physical function, falls, cognitive impairment, and mortality (Ancoli-Israel, 2009). Insomnia is often comorbid with medical and psychiatric illness, such as renal disease, nocturia, cerebrovascular disease, gastrointestinal disease, respiratory disorders, chronic pain and arthritis, neurological diseases, menopause cardiovascular disease, anxiety and depression, as well as multiple medications use in the elderly (Neikrug and Ancoli-Israel, 2010). There are also other factors affecting the ability to sleep in older adults including intake of alcohol, caffeine, and nicotine; circadian rhythm disturbances; and primary sleep disorders, such as SDB, RLS, and RBD (Ancoli-Israel, 2009). While medications are traditionally used to treat insomnia, recent studies have shown that behavioral treatments are more effective and, thus, recommended as the first-line treatment option. In some instances, a combined approach may provide for better

outcomes (Neikrug and Ancoli-Israel, 2010). It is of utmost importance to make the correct medical and psychiatric diagnoses and treat these problems along with appropriate management of the underlying sleep disturbances in older adults (Ancoli-Israel, 2009).

Sleep-Disordered Breathing

SDB is more common in older adults compared to younger adults. Adults 65–90 years of age had a threefold higher prevalence rate than middle-aged adults (Colten and Altevogt, 2006). The prevalence rates of SDB in the elderly were around 55–70% (Bloom et al., 2009; Crowley, 2011; Neikrug and Ancoli-Israel, 2010). Older adults with SDB may also report insomnia, nocturnal confusion, psychomotor function, and daytime cognitive impairment including difficulty with attention and short-term memory loss (Crowley, 2011; Launois et al., 2007). SDB has been associated with nocturia, arterial hypertension, heart failure, atrial fibrillation, diabetes, and stroke, conditions that are more common in the older population (Buchner et al., 2007). Depression has also been found as a common comorbidity in women with SDB (Shepertycky et al., 2005). Older adults are rarely considered candidates for surgery and CPAP is the best approach and first-line treatment for most elderly patients (Bloom et al., 2009; Neikrug and Ancoli-Israel, 2010).

RLS/PLMS

PLMS and RLS are both common in the older adult. The prevalence of RLS/PLMS increases significantly with age, which is experienced by up to 15–34% over the age of 60 years (American Academy of Sleep Medicine, 2005; Cuellar et al., 2007; Neikrug and Ancoli-Israel, 2010). Increasing prevalence of RLS with age may also occur in association with the increasing presence of secondary causes in the aging population, such as age-related declines in dopamine receptors, iron deficiency, and renal failure (Bloom et al., 2009; Crowley, 2011). At the spinal level, lumbosacral narrowing has been reported in some older adults with RLS/PLMS, which is consistent with other data suggesting proprioceptive feedback of limb position is important in the initiation and termination of episodes (Crowley, 2011). Other systemic factors have been proposed, including venous insufficiency in the lower limbs, increased parasympathetic nervous system activity, and iron-deficiency anemia. The recommended treatments for RLS/PLMS in elderly is similar with adults as mentioned before in this article.

REM Sleep-Behavior Disorder

RBD is an important REM sleep parasomnia commonly seen in elderly individuals, which is characterized by abnormal behaviors emerging and intermittent loss of muscle hypotonia or atonia during REM sleep that cause injury or sleep disruption (American Academy of Sleep Medicine, 2005; Chokroverty, 2010). RBD is a male-predominant disorder that emerges after the age of 50 years (American Academy of Sleep Medicine, 2005). The prevalence in the elderly population has been reported around 0.5% (American Academy of Sleep Medicine, 2005). It is seen with increasing prevalence in patients with neurological or neurodegenerative disorder, particularly Parkinson's disease, multiple system atrophy, dementia with Lewy body, narcolepsy, and stroke. PSG demonstrates intermittent loss of REM sleep-associated muscle atonia, with the patient manifesting complex, often violent motor activity associated with dream mentation (Bloom et al., 2009; Chokroverty, 2010). Treatment of RBD involves pharmacologic treatment (e.g., clonazepam and levodopa) and interventions that address environmental safety (Bloom et al., 2009).

Circadian Rhythm Sleep Disorders

In the older adult, factors associated with aging are thought to contribute to the desynchronization of rhythms. The circadian pacemaker itself degenerates with age, which results in less robust rhythms (Reid et al., 2004). With age there is also a gradual decrease in rhythm amplitude, which likely contributes to less consistent periods of sleep–wake across the 24-h day (Reid et al., 2004). The endogenous secretion of melatonin at night is also reduced with age, which results in a weaker circadian rhythm. Therefore, the combination of age-related changes in sleep and circadian rhythm regulation paired with decreased levels of light exposure and activity contribute to the development of circadian rhythm-based sleep disorders in older adults (Bloom et al., 2009). The most common clinical consequence of changes in circadian network of old adults is the advanced sleep phase disorder (ASPD). In middle- to older aged adults, the prevalence of ASPD is estimated at 1–7% (Ando et al., 2002; Bloom et al., 2009). This advanced phase results in sleep and wake times that are several hours earlier than conventional and desired times (American Academy of Sleep Medicine, 2005). Older adults, therefore, feel sleepy in the early evening and awaken in the very early morning hours. Sleep during these times is often normal, but out of sync with the environment. A combination of good sleep hygiene practices and methods to delay the timing of sleep and wake times is usually recommended for the treatment of ASPD (Bloom et al., 2009).

Summary

Although sleep disorders medicine is a relatively young discipline, the understanding of it is evolving at a rapid rate (Roehrs and Roth, 2004). This evolution is seen in the development of diagnostic systems, pathophysiology understanding, signs and symptoms, and finally in the treatment of sleep disorders and comorbid conditions. Treatment of sleep disorders can result in fewer complications of chronic illnesses, increased quality of life, and lower health care costs. It is important for all practicing physicians to understand the implications of disrupted sleep in different age groups and be able to assess accurately and intervene to improve health outcomes and quality through the life span of human beings.

Abstract

Disturbed sleep is a risk factor for many diseases, among others cardiovascular and psychiatric disorders, with depression and anxiety disorders being most closely related to insomnia. In healthy young subjects, sleep consists of rapid-eye-movement (REM) and non-REM sleep periods that alternate in a cyclic fashion. Sleep abnormalities in patients with major depressive disorders, for example, can be classified as difficulties of sleep continuity, abnormal sleep architecture, and disinhibition of REM sleep. This article gives an overview of neurobiological mechanisms underlying the sleep changes in psychiatric disorders and presents implications for sleep related biomarkers of major depression.

Introduction

Complaints of too little (insomnia) or too much sleep (hypersomnia), or of sleep that is not restorative enough, are termed dyssomnias. About one-third of the general population reports insomnia symptoms, with an increased prevalence in women and the elderly. Disturbed sleep is a risk factor for many diseases, among others type II diabetes mellitus, cardiovascular diseases (Grandner et al., 2012), and psychiatric disorders, with depression and anxiety disorders being most closely related to insomnia. In addition, poor sleep leads to impaired daytime performance in several cognitive domains and a strongly enhanced proneness to accidents. Since chronic dyssomnia most often occurs as a comorbid diagnosis, a thorough evaluation of the patient and his/her sleep complaint is a prerequisite for accurate diagnosis and effective treatment.

The diagnosis of insomnia is based upon the patient's subjective complaint of sleeping too little. Patients report difficulties in initiating or maintaining sleep or of non-restorative sleep, i.e., not feeling well rested after sleep that is apparently adequate in amount. Insomnia may occur as primary or secondary disorder due to another psychiatric condition, a general medical condition, and/or substance misuse. The prevalence of primary insomnia relative to secondary insomnia is actually quite rare.

Hypersomnia includes complaints of excessive sleepiness characterized either by prolonged sleep episodes and/or excessive sleepiness during the day. These symptoms may interfere with social, occupational, and/or other areas of functioning. Like insomnias, hypersomnia may occur as a primary or secondary disorder due to a psychiatric and/or medical condition, and/or substance misuse. Compared to primary sleep disorders, the secondary sleep disturbances are more common among patients in a psychiatric practice or hospital. This is particularly important to bear in mind when evaluating a patient with sleep complaints. Dyssomnia is often associated with psychiatric disorders, such as depression, schizophrenia, anxiety disorders, or personality disorders, and misuse of drugs and/or alcohol. Whenever possible, it is clinically useful to assess which is the primary and which is the secondary disorder. This will guide the treatment and improve preventive measures.

Frequency and Risk Factors

Sleeping problems are among the most frequent complaints a general practitioner must deal with. According to epidemiological studies, 19–46% of the population report sleeping problems, of which 13% suffer from moderate or severe disturbances. In terms of the narrow definition of diagnostic criteria, that is, initial insomnia, interrupted sleep, and disturbance of daily well-being, 1.3% of the population suffers from somnipathy (Holsboer-Trachsler and Kocher, 1996). An aging society, the lifestyle of modern civilization including tension, stress, solitude, shift work, and liability for stress related disorders are major risk factors for disturbed sleep. It has been observed that insomniacs reported more medical problems than good sleepers and had twice as many doctor's visits yearly than good sleepers. Furthermore, in severe insomniacs compared to good sleepers, it was found that insomniacs were hospitalized twice as often as good sleepers over the previous 12 months. It was also observed that insomniacs consumed more medication than good sleepers for various treatments.

A World Health Organization (WHO) collaborative study in 15 different countries found that insomnia is more common in females and increases with age. Indeed, it is thought that half of the population over 65 years of age suffers from chronic sleep disturbances. The WHO study also found that 51% of people with an insomnia complaint had a well-defined International Classification of Diseases-10 (ICD-10) mental disorder (e.g., depression, anxiety, alcohol problems). Two prospective studies in a population of younger and elderly subjects showed that individuals who suffered from insomnia were more than three times as likely to develop a major depression compared to those without sleep problems. A similar result was observed for alcoholism.

In particular, depression and anxiety disorders show a high comorbidity with insomnia. For example, insomnia is present in 70% of mood disorders, preceding the emergence of the latter in nearly half of the cases and not only incurs risk for onset, but also for relapse, recurrence, severity, and treatment of a depressive episode. While disturbed sleep has traditionally been viewed as a mere symptom of these disorders, more recent evidence suggests that insomnia and psychiatric diseases may rather be seen as separate but closely inclined disorders.

Regulation of Normal Sleep

The quantity and quality of sleep is measured with polysomnographic recordings (PSG) that include the electroencephalogram (EEG), electromyogram (EMG), and electrooculogram (EOG). In healthy young subjects, sleep consists of rapid-eye-movement (REM) and non-REM sleep periods that alternate in a cyclic fashion. During the transition from drowsiness to light sleep, a slowing of EEG activity occurs, which marks sleep stage 1. In the following sleep stage 2, sleep spindles and K-complex wave forms appear. Slow-wave sleep (SWS) is characterized by synchronized slow waves that define the sleep stages 3 and 4 (Rechtschaffen and Kales, 1968). REM sleep is characterized by a faster EEG activity, horizontal rapid eye movements, and hypotonus of skeletal muscles (**Figure 1**). The first REM sleep period appears usually after approximately 90 min after the first non-REM period. The major amount of SWS is found before the first REM period. While the first REM period is relatively short, duration of later REM periods increases. One sleep cycle consists of one episode of non-REM sleep and one of REM sleep. In healthy subjects, four to five sleep cycles occur during the night. Growth hormone (GH) is usually secreted during the first non-REM period, whereas cortisol secretion rises during the second half of the night and appears to be associated with increased amount of REM sleep.

At least three major processes are involved in the regulation of normal sleep. According to the two-process model of sleep regulation (Borbély and Achermann, 1999), sleep and wakefulness are influenced by both a homeostatic and a circadian process that interact in a complex way. The homeostatic Process S (related to SWS) increases with the duration of wakefulness prior to sleep onset and augments sleep propensity. The circadian Process C, driven by the internal clock located in the suprachiasmatic nuclei, describes the daily cycle of sleepiness and wakefulness and is related to REM sleep. The third process is the ultradian rhythm of non-REM and REM sleep.

On the neuroanatomical level, the different sleep states are triggered by distinct sets of respective brain regions and local activation patterns of groups of neurons in which sleep-regulating endogenous substances modulate sleep–wake behavior (Saper et al., 2005). While wakefulness is modulated

Figure 1 Sleep stages. Rechtschaffen, A., Kales, A., 1968. A Manual of Standardized Terminology, Techniques and Scoring System for Sleep Stages of Human Subjects. Department of Health, Education and Welfare, Neurological Information Network, Bethesda.

by a variety of factors, sleep is promoted by a relatively small amount of sleep-promoting substances including neuropeptides, biogenic amines, prostaglandins, and cytokines. From an evolutionary point of view, the multifactorial sleep regulation makes perfect sense, since dependence on only one specific neuroanatomical location or single factor would render the vital process of sleeping much more vulnerable. The brain stem and the hypothalamus are particularly important brain regions in sleep–wake regulation. Wakefulness is promoted by the ascending arousal system, a network of cell groups that activate the thalamus, and cerebral cortex. Cholinergic nuclei in the upper pons; monoaminergic cell groups including the tuberomammillary nucleus, raphe nuclei, and locus coeruleus; peptidergic neurons in the lateral hypothalamus; and Gamma-aminobutyric acid (GABA)ergic neurons of the basal forebrain contribute to this system (Figure 2). During non-REM sleep, this system is shut off by a key switch in the hypothalamus, the ventrolateral preoptic nucleus (VLPO) (Figure 3). GABAergic and galalinergic neurons in the VLPO are active during non-REM sleep. The cyclic occurrence of REM and non-REM episodes is regulated by a reciprocal interaction of REM-on and REM-off neurons of the brain stem. Pontine cholinergic or glutamatergic REM-on cells induce and maintain REM sleep

Figure 3 A schematic drawing to show the key projections of the ventrolateral preoptic nucleus (VLPO) to the main components of the ascending arousal system. It includes the monoaminergic cell groups (red) such as the tuberomammillary nucleus (TMN), the A10 cell group, the raphe cell groups and the locus coeruleus (LC). It also innervates neurons in the lateral hypothalamus (LHA; green), including the perifornical (PeF) orexin (ORX) neurons, and interneurons in the cholinergic (ACh) cell groups (yellow), the pedunculopontine (PPT) and laterodorsal tegmental nuclei (LDT). Note that the VLPO neurons lie within the region outlined by von Economo for the anterior hypothalamic lesion that caused insomnia. 5-HT, serotonin; GABA, γ-aminobutyric acid; gal, galanin; NA, noradrenaline; His, histamine. From: Saper, C.B., Scammell, T.E., Lu, J. 2005. Hypothalamic regulation of sleep and circadian rhythms. Nature 437 (7063), 1257–1263.

Figure 2 A schematic drawing showing key components of the ascending arousal system. A major input to the relay and reticular nuclei of the thalamus (yellow pathway) originates from cholinergic (ACh) cell groups in the upper pons, the pedunculopontine (PPT), and laterodorsal tegmental nuclei (LDT). These inputs facilitate thalamocortical transmission. A second pathway (red) activates the cerebral cortex to facilitate the processing of inputs from the thalamus. This arises from neurons in the monoaminergic cell groups, including the tuberomammillary nucleus (TMN) containing histamine (His), the A10 cell group containing dopamine (DA), the dorsal and median raphe nuclei containing serotonin (5-HT), and the locus coeruleus (LC) containing noradrenaline (NA). From: Saper, C.B., Scammell, T.E., Lu, J., 2005. Hypothalamic regulation of sleep and circadian rhythms. Nature 437 (7063), 1257–1263.

by phasic activation of occipital cortical regions by the thalamic lateral geniculate body by ponto–geniculate–occipital waves. During wakefulness and non-REM sleep, REM-on cells are inhibited by GABAergic neurons of the deep mesencephalic reticular neurons. A simplified neuroanatomy of sleep–wakefulness is shown in Figure 3. Functional imaging studies revealed that the brain exhibits widespread deactivations during SWS, while REM sleep is associated with increased cerebral blood flow in the thalamus, visual areas, and limbic regions, as well as reduced activity in the dorsal lateral prefrontal cortex (DLPFC), parietal cortex, and the precuneus. These activation patterns seem to correlate with dreaming. While the activation of visual association areas corresponds to dream imagery, activation of the amygdala is in line with dream emotionality, and deactivation of the DLPFC is in accordance with the lack of insight and volition typically experienced in dreams.

Extensive evidence suggests that an important function of sleep is to restore neural capacity within cells and neurocircuitries. Hormones serving restoration and cell growth like GH and prolactin increase their blood level during sleep and important immunological processes are enhanced during sleep. Sleep is not only essential for neural restoration, but also

for memory consolidation and integration (Diekelmann and Born, 2010), emotion regulation, and the preparation for waking life with distinct bidirectional links between sleep and metabolism systems.

Sleep and Psychiatric Disorders

Polygraph sleep research helped paving the way to the modern age of scientific, biological psychiatry. Much of the early sleep research beginning in the mid-1960s was descriptive mapping of events taking place during sleep and laid out the currently rich picture of polysomnographic features in the different psychiatric disorders. Although many of the objective sleep abnormalities associated with psychiatric disorders appear not to be diagnostically specific, these studies have also established sleep measures as neurobiological windows into the underlying pathophysiology associated with psychiatric illnesses. Psychiatric disorders are among the most common primary causes of secondary sleep complaints, particularly of insomnia. Sleep abnormalities may be caused by central nervous system abnormalities associated with psychiatric illnesses as well as by accompanying behavioral disturbances. Patients with depression, anxiety disorders, misuse of alcohol or drugs, schizophrenia, dementia, and personality disorders may complain of difficulty in falling asleep, staying asleep, or of inadequate sleep. Although specific sleep patterns are not necessarily diagnostic of particular psychiatric disorders, there are relationships between certain sleep abnormalities and categories of psychiatric disorders (**Table 1**). Reviews of the literature on sleep in psychiatric disorders documented that findings for patients with affective disorders differed most frequently from those of normal controls (Benca et al., 1992; Steiger and Kimura, 2010).

Sleep Abnormalities in Depression

Among patients with depression, more than 70% complain of insomnia, whereas some suffer from hypersomnia. Sleep abnormalities in patients with major depressive disorders, as assessed by laboratory studies, can be classified as difficulties of sleep continuity, abnormal sleep architecture, and disruptions in the timing of REM sleep. Sleep initiation and maintenance difficulties include prolonged sleep latency (sleep onset insomnia), intermittent wakefulness and sleep fragmentation during the night, early morning awakenings with an inability to return to sleep, reduced sleep efficiency, and decreased total sleep time. With regard to sleep architecture, abnormalities have been reported in the amounts and distribution of non-REM sleep stages across the night, and include increased shallow stage 1 sleep and reductions in the amount of deep, slow-wave (stages 3 and 4) sleep. REM sleep disturbances in depression include a short REM latency (<65 min), a prolonged first REM sleep period, and an increased total REM sleep time, particularly in the first half of the night. While REM latency is clearly affected by age, REM density, in contrast, shows no variation with age, and is enhanced in all investigated age groups in depressed patients. Two studies comparing groups of healthy volunteers and of patients with major depression, anorexia nervosa, and bulimia showed that REM density was enhanced in the depressed patients only, whereas other sleep-EEG variables did not differ. The comparison of patients with depression, never depressed patients with a panic disorder, and healthy volunteers showed that REM sleep duration and REM density were elevated and SWS was reduced only in the patients with depression. REM latency was shortened in both groups of patients when compared to the healthy volunteers and thus appears to be less specific for depression (Lauer et al., 1992).

In the Munich vulnerability study, a prospective high-risk design was applied, that aimed to identify premorbid vulnerability factors for affective disorders (Lauer et al., 1995). Subjects with a positive family history for affective disorders among first degree relatives were investigated. These high-risk individuals who up to the time of the study examination had no psychopathological sign or symptom of depression were compared to healthy volunteers with a negative family history for this or other psychiatric disorders. In the high-risk subjects at the index investigation, REM density was enhanced and the amount of SWS during the first non-REM period was decreased. At a follow-up about 4 years later, these observations were stable (Modell et al., 2002). Every forth subject of the initial sample of high-risk subjects of this study developed an affective disorder during the follow-up period, which is more than twofold the average disease risk. This supports the view that specific traits are closely associated with inherited risk for depression. In these affected high-risk subjects, an increased REM density during the total night and during the first REM period was found in the premorbid sleep EEG. These observations confirm that increased REM density meets all requirements of a vulnerability marker for affective disorder, as it is found in patients with acute depression and in patients after remission. It occurs in healthy high-risk subjects for affective disorders. It is stable over time, and it is predictive for the occurrence of depression and relapse (Hatzinger et al., 2004). REM density has thus been proposed as an endophenotype in family studies and as a biomarker identifying those patients that benefit from specific treatments (Holsboer and Ising, 2010). Simultaneous investigation of sleep EEG and nocturnal hormone secretion showed that in young healthy subjects during the first half of the night SWS and the major peak of GH secretion during 24 h preponderate, whereas the

Meta-analysis by Benca, R.M., Obermayer, W.H., Thisted, R.A., Gillin, J.C., 1992. Sleep and psychiatric disorders: a meta-analyis. Archives of General Psychiatry 49, 651–668.

second half of the night is dominated by REM sleep and the secretion of the hormones of the hypothalamic–pituitary–adrenocortical (HPA) system, corticotrophin (ACTH) and cortisol. During normal aging and during an episode of depression, changes of sleep-endocrine activity occur. As outlined above, sleep-EEG changes in depression include disinhibition of REM sleep (shortened REM latency, prolonged first REM period, elevated REM density), impaired non-REM sleep (reduced time spent in sleep stage 2 and SWS), and changes of sleep continuity (prolonged sleep latency, frequent nocturnal awakenings, and early morning awakening). Similarly, during aging more shallow sleep develops. ACTH and cortisol secretion are elevated in depressed patients. The amplitude of the nocturnal course of these hormones is dampened in the elderly resulting in an elevated nadir. GH secretion is blunted during aging and in a depressive episode as well. The sleep-endocrine pattern in young healthy subjects and its changes related to depression and aging suggest that there exist endogenous factors, which are common regulators of sleep EEG and hormones, linking, for example, SWS and GH or HPA activity and REM sleep, respectively (Steiger and Holsboer, 1997). The integrated model of normal and impaired peptidergic sleep regulation is summarized in **Figure 4**.

Sleep Abnormalities in Anxiety and Post-traumatic Stress Disorder

Anxiety disorders are often associated with sleep disturbances that exacerbate the symptoms and contribute to relapses (Mellmann, 2006). Anxiety and sleep problems are frequently comorbid conditions particularly in older people (Magee and Carmen, 2010). Post-traumatic stress disorder (PTSD), a chronic disorder caused by a traumatic event and characterized by hyperarousal, intrusions, and avoidance of trauma-related stimuli is closely related to sleep (American Psychiatric Association, 2000). Sleep disorders such as insomnia and nightmares often occur in PTSD and may exacerbate PTSD symptoms during daytime and sleep (Spoormarker and Montgomery, 2008). Insomnia is often a residual symptom after treatment of PTSD (Nappi et al., 2012). Sleep related breathing disorders and periodic limb movements are also prevalent in PTSD. A meta-analysis of polysomnographic studies in PTSD found reduced SWS, increased stage 1 sleep, and increased REM density in PTSD patients compared to controls (Kobayashi et al., 2007). PTSD patients often show REM fragmentation, which includes more but shorter REM periods that have been found to be predictive of PTSD symptom severity. Since involuntary memory intrusions are key symptoms in PTSD, drug treatment of PTSD-associated sleep disturbances may also impact on flashback of traumatized memories (Nappi et al., 2012).

Neurobiology of Sleep: Relevance to Psychiatric Disorders

Inspired by the growing knowledge of the underlying neurobiology of sleep, investigators proposed theories into the pathophysiology of psychiatric disorders. Because depression has been studied more than any other psychiatric syndrome in recent decades, the models have attempted to explain features of sleep in depression, such as short REM latency, decreased delta sleep, and the antidepressant effects of sleep deprivation in depressed patients. Among the most prominent models of sleep changes in depression are the cholinergic–aminergic imbalance hypothesis for depression, the two-process Model of sleep regulation, the phase-advance Hypothesis, the overarousal hypothesis, the REM sleep hypothesis, and the contribution of the HPA system to sleep-EEG changes in depression. Moreover, some of the sleep-EEG parameters have been suggested as biomarkers of treatment response and long-term course of depression.

The 'cholinergic–aminergic imbalance hypothesis' (Janowsky et al., 1972) for depression postulates that depression arises from an increased ratio of cholinergic to aminergic neurotransmission in critical central synapses. Because various features of the sleep of depressed patients (decreased REM latency and delta sleep) have been simulated in normal volunteers by pharmacological probes, the reciprocal interaction hypothesis from basic sleep research and the cholinergic–aminergic imbalance model from clinical psychiatry have been correlated. The reciprocal interaction model assumes that the cycling alternating pattern of non-REM and REM sleep is under the control of noradrenergic/serotonergic and cholinergic neuronal networks. Linking these concepts, it is suggested if depression results from diminished noradrenergic and serotonergic neurotransmission, cholinergic activity would be expected to increase and lead therefore to the sleep disturbances of depression.

Among other neurotransmitters, serotonin plays a role in the pathophysiology of depression and its treatment; most antidepressants ultimately lead to an enhancement of serotonergic neurotransmission that is believed to be associated with clinical improvement. Depression is associated with a disinhibition of REM sleep (shortened REM latency, increased REM density) and serotonin leads to a suppression of REM sleep. Furthermore, there is evidence that the antidepressant effect of sleep deprivation is related to a modification of serotonergic neurotransmission, thus sleep regulation and depression share common physiopathological mechanisms at the serotonergic level. According to the 'two-process model of sleep regulation,' depression is thought to result from, or is associated with, a deficiency of Process S. This model was supported by evidence that EEG power density in the delta frequencies was decreased during sleep in depressed patients compared with controls and by the fact that sleep deprivation increases both Process S and mood. In the extended 'two-process model of sleep regulation,' the interaction of hormones with EEG features has been integrated. Preclinical investigations and studies in young and elderly normal controls and in patients with depression demonstrate that neuropeptides play a key role in sleep regulation. As an example, growth hormone-releasing hormone (GHRH) is a common stimulus of SWS and GH release, whereas corticotropin-releasing hormone (CRH) exerts opposite effects. It is suggested that an imbalance of these peptides in favor of CRH contribute to changes in sleep EEG and endocrine activity during depression. Based on the findings that the HPA axis is disregulated in depression, and that CRH produces EEG-sleep changes reminding to depression on one

Figure 4 Model of normal and impaired peptidergic sleep regulation. During the first half of the night the influence of GHRH preponderates resulting in the high amounts of SWS and GH. During the second half of the night CRH and its cofactor somatostatin dominate. Changes in the GHRH/CRH balance during depression and aging result in similar alternations of sleep-endocrine activity. GHRH = growth hormone-releasing hormone, CRH = corticotrophin-releasing hormone, SRIF = somatostatin. Adapted from: Steiger, A., 1995. Schlafendokrinologie. Der Nervenarzt 66, 15–27, Figure 2.

hand (SWS reduction, REM sleep disinhibition), and that the somatotrophic system reciprocally interacts with the HPA system (decreased GHRH and SWS), it has been postulated that deficient Process S is associated with deficient GHRH and an overdrive of CRH. Although abnormally high values of cortisol secretory activity normalize after recovery from depression, GH release and several characteristic disturbances of the sleep EEG may remain unchanged. These putative trait-dependent alterations suggest that strategies aiming at restoration of these sleep changes are worthy of exploration for their potential antidepressant effect.

The depressed state appears not only to be associated with a disturbance of sleep–wake homeostasis, but also of circadian function or of their interaction. The 'phase-advance hypothesis' (MacLean et al., 1986) suggests that the phase position of the underlying circadian oscillator is 'phase advanced' relative to the external clock time. This is supported by studies showing that short REM latency (one of the key sleep-EEG changes in depression) could be simulated in normal controls by appropriate phase shifts of hours in bed.

As mentioned above, sleep deprivation has potent antidepressant effects in more than half of all depressed patients. This observation has prompted the hypothesis that depressed patients are 'overaroused.' Later, the 'overarousal hypothesis' has been forwarded and was supported by psychological self-rating studies suggesting that clinical improvement to sleep deprivation in depression may be associated simultaneously with subjective feelings of more energy (arousal), less tension, and more calmness (dearousal). Other data consistent with this hypothesis include the short, shallow, and fragmented sleep patterns; lowered arousal thresholds; and elevated nocturnal core body temperature often seen in depressed patients. This hypothesis has been tested by means of studies of localized cerebral glucose metabolism with 18F-deoxyglucose positron emission tomography in separate studies in depression, sleep deprivation, and the first non-REM period of the night. In these studies, it was found that elevated brain metabolism prior to sleep deprivation predicted clinical benefits in depressed patients and that normalization of these measures is associated with clinical improvement. It was also found that local cerebral glucose metabolism in cingulate and amygdala at baseline was significantly higher in clinical responders than in nonresponders or normal controls. Furthermore, it was shown that glucose metabolic rate was increased during the first non-REM period in depressed patients compared with normal controls. Moreover, these studies demonstrated significant 'hypofrontality,' that is, reduced ratio of frontal to occipital activity, compared with normal controls.

The 'REM sleep hypothesis' of depression has been based on the findings that REM sleep is enhanced in depression and that virtually all antidepressant drugs suppress REM sleep. Early, however not replicated, studies have shown that a sustained remission from depression may be achieved by selective REM sleep deprivation carried out repeatedly every night during about 2 weeks. This treatment modality was not followed because the long-term REM sleep deprivation was too demanding exhausting for the patients. The so-called 'sleep-phase advance' protocol that is scheduling sleeping times in a way that minimizes the occurrence of REM sleep, has been shown to produce a sustained antidepressant effect. However, also this treatment modality is demanding for both the patients and the institutional staff and therefore rarely applied.

Sleep EEG and HPA System: Markers of Antidepressant Treatment Outcome

Some of the above mentioned sleep-EEG variables were suggested as biomarkers and predictors of antidepressant therapy response and clinical outcome (Steiger and Kimura, 2010; Baskaran et al., 2012). Increase of REM latency after 2 days of treatment with amitriptyline was correlated with the clinical outcome after 4 weeks. In a prospective study with the selective serotonin reuptake inhibitor (SSRI) paroxetine and the serotonin reuptake enhancer tianeptine, REM density after 1 week of treatment was a predictor of treatment response (Murck et al., 2003). A follow-up study in depressed patients who had previously participated in an earlier trial with trimipramine treatment revealed associations between sleep-EEG parameters and treatment outcome as well as the long-term course of depression: low sleep continuity, low SWS, and elevated REM density were associated with the number of previous depressive episodes. Increased REM density and decreased SWS at the end of the treatment trial were related to an increased recurrence rate during the follow-up period, indicating a strong association between long-term course of depression and these markers of the sleep EEG (Hatzinger et al., 2004). These sleep-EEG variables were related to impaired HPA system regulation as shown by abnormal dexamethasone/corticotropin-releasing hormone (DEX/CRH) test results. Noteworthy, another study suggested that a failure to normalize the DEX/CRH test within 2.5 weeks of antidepressant treatment is an independent predictor for nonresponse (Ising et al., 2007). Interestingly, associations between unfavorable sleep-EEG patterns, enhanced HPA activity, and more difficult behavioral psychosocial dimension were found already in otherwise healthy kindergarten children (Hatzinger et al., 2008), indicating an interplay between sleep and HPA axis regulation in a dimensional way rather than only in diagnostic categories of health versus disease. Recently, parameters of EEG cordance during REM sleep, a quantitative EEG measure combining complementary information from absolute and relative power of EEG spectra, were found as an early marker of treatment response that differentiated between responders and nonresponders to antidepressant pharmacotherapy.

Future Perspectives

We have outlined just some aspects of sleep research that are relevant to depression. Linking basic and clinical approaches has been one of the 'royal roads' to the neurobiological underpinnings of psychiatric diseases and their treatment in the past, and to narrow the gap between bench and bedside. In addition to whole night PSG recordings, the search for biomarkers in daytime naps might be a promising research strategy, since it has been shown that even very short naps lead to relapses in patients profiting from therapeutic sleep deprivation. Such short sleep periods thus appear to be very closely

related to the neurobiological mechanisms underlying depression.

Based on the findings that sleep-EEG variables like REM density or certain clusters of variables including markers of HPA axis regulation are able to predict treatment response and long-term course of the disease, there is hope that future treatment of depression will be improved with the support of biomarkers that better reflect the underlying pathology than diagnostic attributions that are based only on clinical symptoms (Holsboer, 2008). A combination of biomarkers derived from polysomnography, complemented by neuroendocrine testing, brain imaging, and genomics are promising tools that may ultimately guide treatment strategies that are tailored to the individual patient.

Abstract

Our 24-hour day is divided into periods of wake and sleep. Sleep itself is divided into periods of rapid eye movement (REM) sleep and non-REM sleep. A large collection of brain areas exist to produce wake and the various sleep states. These brain areas are networked together to coordinate switching between these states. Homeostatic and circadian factors also influence these sleep areas so that sleep occurs at optimal times to meet physiological needs.

Sleep

We spend approximately one-third of our lives asleep. Sleep is a ubiquitous behavior in mammals and birds, and is found in most other vertebrates. Sleep-like states are even observed in invertebrates such as the fruit fly and pond snail. Although the purpose of sleep is debated, it is clear that it serves a necessary role. Sleep is homeostatically regulated, as sleep loss results in an increase drive to engage in sleep and increased sleep duration once sleep is permitted. Furthermore, total sleep deprivation in rodents eventually leads to death after about 3 weeks.

Definitions

Sleep is a natural state of reduced or absence of consciousness. It is characterized by the following features: (1) a species-typical sleep posture, (2) reduced responsiveness to stimuli, (3) reduced movement, and (4) easily reversible (cf hibernation or coma). While sleep is frequently perceived of as synonymous for 'not awake,' it is a heterogeneous behavior, consisting of two major states: rapid eye movement sleep (REM) and non-REM sleep (NREM), each of which exhibits a variety of unique physiological phenomena. Furthermore, organisms typically oscillate between these two sleep states with a regular period. Modern sleep researchers use electroencephalography (EEG) in conjunction with electromyography and electrooculography to objectively define the various stages of sleep based on characteristic brain oscillations, muscle tone, and eye movements. Respiration, cardiovascular function, body temperature, and hormonal activity are also altered depending on the particular stage of sleep.

Rapid Eye Movement Sleep

REM sleep is characterized by rapid and ballistic medial-lateral movements of the eyes. The EEG pattern closely resembles that of an awake individual with high-frequency and low-amplitude activity. For this reason, REM sleep is also known as paradoxical sleep, as the individual is asleep despite exhibiting a wake-like EEG. REM sleep is also characterized by sequential activation in the pons, lateral geniculate nucleus (LGN), and finally occipital cortex, leading to characteristic ponto-geniculo-occipital (PGO) waves. While in REM sleep we experience muscle atonia in our postural muscles. Breathing rate becomes irregular although it generally increases. Body temperature regulation is diminished during REM sleep. Heart rate and blood pressure increase during REM sleep and exhibit more variability in their rate. Dreams are most frequent and vivid during REM sleep.

Non-REM Sleep

NREM sleep is characterized by gradual slowing of EEG frequency and increases in EEG amplitude. It can be subdivided into various stages, depending on the EEG features. Light sleep (Stage 1) exhibits a slight slowing in EEG frequency compared to waking EEG. Stage two exhibits even more slowing and increased amplitude. Additionally, Stage 2 sleep also exhibits brief high-frequency (12–14 Hz) bursts known as sleep spindles, as well as large voltage low frequency waves known as K-complexes. Stages 3 and 4 are also known as slow wave sleep and are characterized by high-amplitude low frequency oscillations. Eye movements are slow and rolling rather than rapid and ballistic. Body temperature, heart rate, and blood pressure all decrease during NREM sleep, and growth hormone is secreted. Muscle tone is maintained during NREM sleep. There is little dreaming activity in NREM sleep, and typically cognitive content is less than what is experienced during REM sleep.

Historical Investigations

Frederick Bremer conducted the first studies examining the neural regulation of sleep (Bremer, 1935). His passive theory of sleep posited that fatigue diminished sensory input to the central nervous system, and that sleep resulted from this decreased sensory input. He used transections of the cat central nervous system to separate the cortex where EEG was recorded from its various inputs. In the encéphale isolé (isolated brain) preparation a cut was made at the level of the medulla, which preserved all input from the cranial nerves. In this case, normal patterns of sleep and wake EEG were observed. Bremer's second preparation was the cerveau isolé (isolated forebrain), which was performed by making the transaction through the midbrain. In this case, there was preserved sensory input from only the olfactory and optic nerves, and a persistent slow wave sleep EEG pattern was observed. Between these two levels of

transaction lies the reticular system in the core of the brain stem. This area receives collateral input from sensory afferents. When stimulated, persistent wake EEG was observed, and when lesioned, a persistent slow wave sleep EEG pattern resulted (Jones, 2010). This latter observation suggested that sensory input was not sufficient to produce wakefulness, as these lesions preserved sensory input to the central nervous system. More modern studies using lesions and stimulation of various forebrain, hypothalamic, and brain stem regions have revealed that sleep–wake regulation involves the coordinated activity of numerous brain regions, and sleep does not simply result from decreased sensory input due to fatigue.

Homeostatic

The timing of sleep has been proposed to be regulated by two factors: a homeostatic factor and a circadian factor (Borbely, 1982). In this model, a sleep-promoting factor (Process S) accumulates during waking. When Process S accumulates to a specific threshold, a sleep drive is initiated. The levels of Process S then degrade during sleep. Upon falling to another threshold, wake is triggered. These thresholds are regulated by the circadian component, such that the levels at which Process S promotes waking and sleep are time-of-day dependent. While the circadian component has been well established (see below), the search for a homeostatic factor has been more problematic. It had been hypothesized that there may be a humoral factor that promotes sleep in a fashion consistent with Process S. Cytokines, such as interleukin-1, do promote sleep, but this likely has to do with promoting sleep to fight off an infection, and they are not likely involved in sleep regulation. A number of observations rule out a humoral factor that accumulates during wake to induce sleep. First, conjoined twins sharing a blood supply do not show synchronized sleep or sleep states. Furthermore, cetaceans, such as the dolphin, and waterfowl are able to exhibit different EEG states in each cerebral hemisphere, with one hemisphere awake while the other exhibits a slow wave sleep EEG pattern.

The nucleotide adenosine does fit the characteristics of a sleep-promoting homeostatic drive (Basheer et al., 2004; Porkka-Heiskanen et al., 1997). Adenosine can be released as a neurotransmitter, but is also found extracellularly as the byproduct of metabolism of adenosine triphosphate. Adenosine generally inhibits the activity of neurons by activating the A1 receptor. Adenosine levels accumulate during wake, particularly in the basal forebrain regions that contain wake-promoting neurons. Caffeine and other xanthines that promote wakefulness do so by acting as adenosine receptor antagonists.

Neural Mechanisms

Three main regions of the central nervous system play roles in regulating sleep and wake: the brain stem, the basal forebrain, and the hypothalamus. Historical investigations highlighted the importance of brain stem structures for the regulation of wake and REM sleep. The basal forebrain regulates wake. Finally, the hypothalamus plays a role in regulating both sleep and wake, as well as the circadian timing of behavioral state and transitions between sleep and wake. A variety of regions and neurotransmitter play a critical role, summarized below and in Table 1.

Wake

Brain Stem

As highlighted by the early transection studies, the brain stem contains a critical wake-promoting area. A number of brain stem regions combine to give rise to the ascending reticular activating system (ARAS). The first structure to be described was the reticular formation at the core of the brain stem extending from the caudal midbrain to the medulla. This structure is critical for producing wake-like states. Stimulation of the reticular formation in the midbrain elicits a wake-like EEG pattern (Moruzzi and Magoun, 1949). Cells in this region discharge when cortical EEG exhibits a desynchronized low-amplitude pattern during either wake or REM sleep (McCarley and Hobson, 1971). Cholinergic neurons in the pedunculopontine and laterodorsal tegmental nuclei (PPT/LDT) that lie just dorsal to the reticular formation in the pons are also critical for wakefulness. Both of these populations appear to play a role in both REM and wake regulation.

Serotonin

Also in the brain stem are monoaminergic populations that participate in regulation of waking as part of the ARAS. Serotonergic cells in the dorsal and median raphe nuclei are most active during wake, less active during NREM sleep, and are silent during REM sleep. While serotonin neurons are active during wake, they are most active during wake states with lower arousal levels such as during repetitive motor behaviors like chewing or grooming. Serotonin agonists inhibit both NREM and REM sleep. However, serotonin also appears to inhibit cholinergic neurons, and thus it is mildly sedating. Serotonergic cells project to many other regions involved in sleep and wake regulation, including ventrolateral preoptic area (VLPO, see below), histaminergic cells in the tuberomammillary

Table 1 Various brain regions involved in sleep–wake regulation, their corresponding neurotransmitters and relative activity during the various behavioral states

nucleus, wake active cells in the basal forebrain, and the circadian clock in the suprachiasmatic nucleus (SCN).

Norepinephrine

Another region of brain stem cells involved in wake regulation is the locus coeruleus, which contains noradrenergic neurons. Like serotonin cells, these neurons are most active during wake, less active during NREM sleep, and silent during REM sleep. They project widely to other areas involved in sleep and wake regulation. They activate cells in the ARAS, serotonergic cells in the raphe, and cholinergic cells in the basal forebrain. Noradrenergic cells also inhibit sleep active neurons in the VLPO and REM active cholinergic neurons in the brain stem.

Basal Forebrain

While brain stem lesions of the ARAS regions initially produce a profound coma-like slow wave sleep state, animals eventually recover an alternating pattern of wake and sleep EEG. This suggests that while the ARAS plays an important role in production of wake, other areas participate as well. The ARAS gives rise to two ascending pathways. The dorsal path projects to the thalamus to regulate cortical arousal, while the ventral path projects to the basal forebrain and hypothalamus where other wake-promoting regions are found.

The basal forebrain contains cholinergic cells that project to the cortex. In particular, the cells in the caudal basal forebrain in regions such as the substantia innominata, nucleus basalis, and preoptic area exhibit higher firing during periods of cortical desynchrony (wake and REM). Activation of cholinergic cells in the basal forebrain increases cortical desynchrony, while inhibition of cholinergic cells here promotes cortical synchrony (Lee and Dan, 2012).

Hypothalamus – Histamine

Histaminergic cells in the tuberomammillary nucleus of the posterior hypothalamus also promote wakefulness. Antihistamine medication used to inhibit allergic reactions or nausea produce drowsiness through blocking H1 receptors. These cells are most active during wake, mildly active during NREM, and silent during REM sleep. These neurons activate cells in the ARAS and inhibit sleep active neurons found in the VLPO. They are activated by input from hypocetin cells in the hypothalamus (see below) and serotonin cells from the raphe nuclei.

Hypothalamus – Hypocretin (Orexin)

The lateral and posterior hypothalamus contains a small population of cells that contain the neuropeptide hypocretin (also known as orexin). These hypocretin cells are critical for normal regulation of wake and sleep, as is evidenced by the sleep disorder narcolepsy. Narcoleptics suffer from sleep attacks and cataplexy (the muscle atonia associated with REM sleep). Most people with narcolepsy have lost the majority of their hypocretin cells, although some heritable forms derive from a mutation in a hypocretin receptor.

Hypocretin cells receive noradrenergic input from the locus coeruleus, as well as cholinergic and serotonergic input. Cholinergic input activates hypocretin cells, whereas serotonin input is generally inhibitory. Noradrenergic input can be either excitatory or inhibitory. Hypocretin cells are active during wake, show diminished activity during NREM sleep, and are silent during REM sleep (Jones, 2005). When active, they excite neurons in a variety of wake active areas, including the tuberomammillary nucleus, cholinergic basal forebrain, locus coeruleus, and reticular formation (Jones, 2010; Sutcliffe and de Lecea, 2002). When activated optogenetically, sleeping animals rapidly wake up (Adamantidis et al., 2007). Optogenetically silencing hypocretin neurons induces slow wave sleep (Tsunematsu et al., 2011). Hypocretin agonists enhance arousal, and even mitigate the negative effects of sleep deprivation on cognitive performance (Deadwyler et al., 2007), while antagonists may be useful to promote sleep in people experiencing insomnia (Neubauer, 2010).

Sleep

Ventrolateral Preoptic Area

The early transections studies highlighted that the forebrain was able to produce slow wave NREM sleep on its own. The location of the major sleep-active neurons is the VLPO. Cell-specific lesions in this region lead to large reduction in sleep, particularly in NREM sleep (Lu et al., 2000). These cells contain the inhibitory neurotransmitters gamma aminobutyric acid (GABA) and galanin. These cells are active during sleep, as assessed by multiunit activity and immediate early gene expression (Brown et al., 2012). Their firing rate is even higher during NREM sleep following sleep deprivation (Szymusiak et al., 1998). Adenosine is able to indirectly activate VLPO neurons by turning off inhibitory input, thus linking the activity of these neurons to a putative homeostatic sleep drive. The VLPO makes reciprocal connections with many components of the ARAS, most notably the histaminergic tuberomammillary nucleus, the noradrenergic locus coeruleus, hypocretinergic cells in the lateral hypothalamus, and the serotonergic raphe nuclei. Acetylcholine and norepinephrine inhibit the activity of VLPO neurons, and serotonin inhibits most VLPO neurons. Histamine and hypocretin appear to indirectly inhibit VLPO neurons by activating local inhibitory interneurons. Conversely, VLPO neurons are able to inhibit most of these areas. It is these mutually inhibitory reciprocal connections that are thought to regulate maintenance of a particular state (e.g., sleep or wake) and transition between states (see flip-flop model below). It is the inhibition of the wake active areas by GABA that is thought to underlie the mechanism of action of benzodiazepine sleeping pills (Jones, 2005).

Median Preoptic Area

The median preoptic area (MnPO) also contains inhibitory GABAergic neurons. While VLPO neurons are most active during sleep, cells in the MnPO appear to be most active in relation to sleep drive. Their firing precedes sleep and is highest during periods of sleep deprivation. These cells also project to many wake active areas, inhibiting their activity. Electrical or chemical activation of the MnPO enhances sleep, whereas silencing of the MnPO enhances wake (Brown et al., 2012).

REM Sleep

REM sleep is a complex state with many unique features. First and foremost, it is a sleep state characterized by unconsciousness

and unresponsiveness. However, cortical activity is wake-like, exhibiting high-frequency, low-power EEG patterns. Some unique electophysiological events occur during REM, such as PGO waves and hippocampal theta activity (4–7 Hz oscillation, Robinson et al., 1977). Additionally, postural muscles are paralyzed during REM sleep. Finally, REM sleep derives its name from unique REMs.

Early transection studies (reviewed in Brown et al., 2012) revealed that cuts between the brain stem and the midbrain eliminated REM sleep electrophysiological patterns in the forebrain (PGO waves, hippocampal theta, low-voltage high-frequency EEG). However, REMs and muscle atonia were preserved, thus highlighting the brain stem as critical for REM sleep regulation.

Cholinergic regions in the brain stem participate in REM sleep. Cells in the laterodorsal tegmental nucleus and pedunculopontine tegmental nucleus are active during both wake and REM sleep, and their firing is correlated with cortical desynchrony. Cells in this region also innervate the thalamus, particularly the lateral geniculate. When these cholinergic brain stem areas are stimulated, PGO wave-like activity can be recorded in the LGN. When these cholinergic brain stem areas are lesioned, PGO waves are lost. Simultaneous recordings in the cholinergic brain stem region and the thalamus during REM sleep reveal that bursting in the LDT/PPT correlates with occurrences of PGO waves.

In rats, glutamatergic neurons just ventral to the LDT/PPT in the sublaterodorsal nucleus (SLD) also appear to be critical for REM regulation. In cats, the homologous cell group is located more caudally, just ventral to the locus coeruleus in the subcoerulear nucleus (SubC). These regions are necessary for muscle atonia, as REM atonia is lost with small discrete lesions of the SLD/SubC. When animals receive larger lesions in these regions, they appear to act out their dreams while in REM sleep. For instance, cats will engage in what looks like predation behavior (stalking and pouncing) while in REM sleep. Cells in the SubC increase their firing prior to atonia, and immediate early gene expression in the SLD is correlated with time spent in REM sleep (Brown et al., 2012; Saper et al., 2010). Electrical stimulation of the SubC can elicit muscle atonia in some cases (Brown et al., 2012). The SLD region also receives input from the VLPO and hypocretin regions of the hypothalamus. Other glutamatergic brain stem regions implicated in REM control are the parabrachial nucleus and precoeruleus regions. These regions project to the forebrain and express immediate early genes during periods of REM sleep (Lu et al., 2006).

Neurons in the reticular formation, particularly in the nucleus pontis oralis (PnO) and nucleus pontis caudalis (PnC), participate in REM regulation. Many cells in these regions are GABAergic and receive cholinergic input from the LDT/PPT. Infusions of cholinergic agonists excite a majority of PnO and PnC neurons, and can induce long periods of REM sleep (Bourgin et al., 1995).

Both serotonergic cells from the raphe and noradrenergic cells from the locus coeruleus appear to inhibit REM sleep. These regions are silent during REM sleep. LDT neurons that are active during REM are silenced when serotonin agonists are applied.

While the circuitry of the brain stem explains much of the neural regulation of REM sleep, areas in the forebrain also appear to participate. Cholinergic neurons in the basal forebrain burst during both wake and REM sleep (Lee et al., 2005), likely contributing to cortical arousal during both of these states. Cells in the extended VLPO region are also involved in REM sleep regulation. While lesions of the central cluster of VLPO cells disrupt primarily NREM sleep, lesions of the medial and dorsal VLPO regions that have more scattered neurons lead to a decrease in REM sleep (Lu et al., 2000). These cells in the extended VLPO show immediate early gene expression that is more highly correlated with REM sleep. These sleep active extended VLPO neurons project to both the locus coeruleus and dorsal raphe, and appear to use the inhibitory neurotransmitter galanin (Lu et al., 2002). These data suggest that the extended VLPO may elicit REM sleep by inhibiting the locus coeruleus and raphe nuclei.

State Regulation

The architecture of sleep and wake is carefully regulated. Species typically exhibit large consolidated bouts of both wake and sleep, and within sleep, animals alternate between consolidated bouts of REM and NREM sleep. As mentioned above, these patterns are modeled in part by the two-process sleep model that contains both a circadian and a homeostatic drive. Actual transitions between wake and sleep, and REM and NREM involve the coordinated change in neural activity of sleep and wake brain regions reviewed thus far.

Circadian

Sleep and wake occur at species-typical times of day. Animals awake at night, such as mice, are nocturnal while those awake during the day, such as humans, are diurnal. Other species exhibit a bimodal activity pattern that tracks dawn and dusk, and are known as crepuscular. The patterning of sleep and wake is controlled by a circadian clock located in the SCN of the hypothalamus (Antle and Silver, 2005). Cells in the SCN are intrinsically rhythmic, due to a molecular clock deriving from autoregulatory transcription–translation feedback loops. The oscillations of these individual clock cells are coordinated, and as a tissue, the SCN provides a temporal signal to the rest of the brain and body to regulate daily oscillations in behavior and physiology. While these circadian rhythms can persist in the absence of time cues, the SCN receives input from the retina so that its oscillations are entrained to the day–night cycle. The SCN outputs to a variety of brain regions involved in sleep and wake regulation, including the VLPO, MnPO, and hypocretin cells. Furthermore, the SCN innervates the subparaventricular zone and dorsomedial hypothalamus, both of which innervate many of the same sleep–wake areas, allowing for modulation of circadian signals (Kriegsfeld et al., 2004; Mistlberger, 2005). The SCN is also able to regulate other areas involved in sleep and wake regulation, such as the histaminergic cells in the tuberomammillary nucleus, through multisynaptic pathways. The SCN also projects to the lateral septum, which regulates the medial septum, which in turn regulates hippocampal theta activity (Bland, 1986).

The SCN is metabolically and electrically most active during the day, regardless of diurnality or nocturnality. The electrical

activity of the circadian clock in rats is also related to sleep state, with elevated activity during REM sleep and lowered activity during NREM sleep (Deboer et al., 2003). Most SCN cells release GABA as their main small molecule neurotransmitter. Most SCN cells also employ one or more peptidergic neurotransmitter as well. These include vasoactive intestinal polypeptide, gastrin-releasing peptide, and arginine vasopressin. The SCN is also able to regulate rhythmicity through a paracrine mechanism, as SCN-lesioned animals regain rhythmicity when they receive fetal SCN grafts that are encapsulated in a material that prevents neuronal reconnection, but allows diffusion of chemical messengers (Silver et al., 1996). Two chemicals have been suggested to participate in this paracrine transmission: transforming growth factor alpha and prokineticine-2 (Mistlberger, 2005).

The circadian clock provides temporal structure to sleep–wake cycles. When the SCN is lesioned, animals still exhibit bouts of sleep and wake, but these bouts are very short and are evenly distributed across the day and night. The circadian clock was originally suggested to promote wake, as it had been observed that arrhythmic animals with SCN lesions exhibited more sleep. One possibility is that more sleep is required once sleep becomes fragmented due to lower sleep efficiency in SCN-lesioned animals. However, the observation of increased sleep in SCN-lesioned animals is not universal, and further studies have since suggested that the circadian clock actively promotes both sleep and wake (Mistlberger, 2005).

On top of regulating behavioral state, the circadian clock can also be influenced by changes in such states. The SCN receives heavy serotonergic innervation from the median and dorsal raphe (Yamakawa and Antle, 2010). Sleep deprivation enhances serotonin output at the SCN (Grossman et al., 2000) and can reset the phase of the circadian clock (Antle and Mistlberger, 2000).

Transitions between States

Wake, REM sleep, and NREM sleep are each associated with activity in specific brain areas, but a mechanism to switch between states is also required. It is the reciprocal innervation patterns between many of these areas that give rise to the brain network that both maintains a particular sleep–wake state and also permits rapid switching between states.

In people, sleep typically lasts for about 8 h. The two-process model explains quite well the timing of sleep onset and offset according to both circadian and homeostatic drives. However, the switching of activity between the various wake and sleep areas needs to be carefully coordinated. A flip-flop model has been proposed that explains how activity of these various areas is coordinated (Saper et al., 2001). The flip-flop switch derives from electrical engineering circuits, and represents a bistable two-path switch. Each state reinforces itself and inhibits the alternate state. In the case of sleep–wake regulation, wake areas are self-reinforcing and inhibit activity in sleep centers, while sleep centers are also self-reinforcing and inhibit activity in wake centers. Circadian and homeostatic factors could influence the activity of wake and/or sleep centers, and would contribute to the trigger to initiate a state transition.

The specific features of the sleep–wake flip-flop switch (**Figure 1**) have noradrenergic signals from the locus coeruleus, serotonergic signals from the raphe and histaminergic signals from the tuberomammillary nucleus on the wake side of the circuit, and GABAergic signals from the VLPO on the sleep side of the circuit. Signals from the hypocretin cells in the lateral

Figure 1 Flip-flop model of regulation of sleep–wake. (a) During wake, the wake centers (raphe nuclei, locus coeruleus (LC), and tuberomammillary nucleus (TMN)) inhibit the activity of the sleep center in the ventrolateral preoptic area (VLPO). The hypocretin neurons in the lateral hypothalamus (LH) reinforce activity in the wake areas. The circadian clock in the suprachiasmatic nucleus may promote wake and inhibit sleep. The homeostatic drive (thermostat, representative of adenosine levels in the basal forebrain) is low, although accumulates during wake. (b) During sleep, the sleep center in the VLPO area inhibits wake areas including the raphe nuclei, TMN, LC, and LH. The circadian clock may inhibit wake and promote sleep. The homeostatic drive is high due to high levels of adenosine in the basal forebrain. Modified from Brown, R.E., Basheer, R., McKenna, J.T., Strecker, R.E., McCarley, R.W., 2012. Control of sleep and wakefulness. Physiological Reviews 92, 1087–1187.

hypothalamus maintain activity in the wake centers, while adenosine serves as a homeostatic signal that influences the activity of the VLPO to promote sleep. The circadian clock can actively promote the state of the flip-flop circuit by directly or indirectly regulating the activity of the hypocretin cells and the VLPO. The key feature of such a flip-flop switch is that animals in a wake state will tend to stay awake, and animals in a sleep state will tend to stay asleep. It is only with significant input to the other side of the flip-flop circuit that the state can be switched, and when such switches occur, they occur rapidly.

Within sleep there are also neural networks that regulate switching between REM and NREM. This switching occurs with an ultradian REM/NREM cycle of about 90–100 min. Typically sleep is initiated through NREM, and bouts of NREM are longer and the cortical EEG shows larger amplitudes and lower frequencies in the first half of the sleep phase. REM bouts get longer as the sleep phase progresses. A number of models have been proposed to account for this switching. Similar to the sleep–wake control, a flip-flop model has also been proposed, where areas active during REM (cholinergic cells) and areas silent during REM (serotonergic and noradrenergic cells) are mutually inhibitory (Lu et al., 2006). Others have suggested the use of a Lotka–Volterra model (McCarley and Hobson, 1975). In classic Lotka–Volterra systems, oscillations in predator–prey population sizes are modeled with oscillations in predator population size lagging prey population sizes. The prey numbers are self-reinforcing, and also promote increases in predator populations. Predator population, however, are inversely related to prey populations (i.e., high predator numbers leads to low prey, and low predator number leads to high prey numbers). The result is a stable oscillation in both predator and prey population sizes. When this model is applied to regulation of REM and NREM, realistic alternations between these states emerges. Specifically, in the case of sleep regulation, the Lotka–Volterra model uses activity of REM-on areas as the prey component, and the activity of REM-off areas as the predator. In this way, areas active during REM slowly activate the REM-off areas, such that their activity eventually reaches a sufficient level to inhibit the REM-on areas. Specifically, serotonergic and noradrenergic cells are active during wake, but slowly reduce their firing during NREM sleep. This gradually disinhibits the cholinergic REM-on cells. When the REM-on cholinergic cells become active, they slowly activate the serotonergic and noradrenergic cells. The REM-on neurons also positively reinforce their own activity to help maintain the REM state until activity in the serotonergic and noradrenergic cells is sufficient to turn off the cholinergic REM-on cells (Brown et al., 2012; McCarley and Hobson, 1975).

Summary

The brain has a large network of areas that orchestrate behavioral state, using a wide variety of neurotransmitters. Brain stem, hypothalamic, and basal forebrain regions are critical for producing wake, sleep, and REM sleep. While early work highlighted the role of brain stem regions for regulating sleep and wake, the hypothalamus and basal forebrain are now recognized as being particularly critical for regulating sleep and wake.

Slow Food as a Social Movement

Koen van Bommel, VU University, Amsterdam, The Netherlands
André Spicer, Cass Business School, City University, London, UK

Abstract

This article examines the development of the Slow Food movement. The first section examines the history of the movement and the main changes since its start in 1989. The second focuses on more general themes that account for Slow Food's development. We first examine Slow Food's transformation from a gastronomic to an eco-gastronomic movement and subsequently discuss the movement's potential to create markets around authenticity. Finally, we examine the implications of the increasing globalization of the movement as it broadened its initial Italian focus toward other developed as well as developing countries.

Preoccupation with food, its origins and distribution, has become an emblematic feature of current times among consumers, producers, civil society, and policy makers. Whereas famine and malnutrition remain problems of primary concern in some areas, overproduction and waste are paramount in others. More generally, the dominance of monocultures, chemicals, and large-scale global production of standardized food has been put into question as it potentially ruins taste, health, our environment, the livelihood of farming communities, and overall creates disenchantment with the experience of cooking and eating (Bové and Dufour, 2002; Honore, 2004; Ritzer, 2011; Schlosser, 2002). In response, movements advocating organic food (Skinner, 2007) and fair trade food (Reinecke, 2010) have proliferated. Arguably, one of the most prolific examples of resistance against hegemonic food regimes has been the Slow Food movement and its quest for 'good, clean, and fair' food. What started out as mainly an Italian gastronomic movement attracting foodies has become a global movement that appeals to a broader constituency of environmentalists and people concerned with fair trade and social justice.

As of 2013, Slow Food has around 1500 local chapters (called convivia) and over 100 000 members across more than 160 countries. Founded in 1989, the Slow Food movement has been strongly embedded in its Italian roots. National associations soon emerged in Germany (1992) and Switzerland (1993) to coordinate the activities and convivia in these countries. After the turn of the century, further national associations were set up in the United States (2000), Japan (2004), the United Kingdom (2005), and the Netherlands (2008). Slow Food has its headquarters still in the small town of Bra in the Italian Piedmont region from where global initiatives and projects are coordinated. The association is essentially governed by its International Council and Executive Committee under the continuing presidency of founder Carlo Petrini. An official member-based association in its own right, it can also be seen as a social movement (see e.g., Andrews, 2008; Van Bommel and Spicer, 2011), as it comprises "collective challenges by people with common purposes and solidarity in sustained interaction with elites, opponents and authorities" (Tarrow, 1994: pp. 3–4) and taps into "… a much broader backlash against the high-speed, high-turnover culture of the global food industry" (Honore, 2004: p. 57). We examine the history of Slow Food and focus on three themes that help to explain the development of the Slow Food movement: (1) its broad shift from a gastronomic to an eco-gastronomic movement; (2) the importance of an identity of authenticity in relation to the emergence of a new market for Slow Food; and (3) the implications of the increasing globalization of the movement.

A History of the Slow Food Movement

Early Years

The Slow Food movement's official narrative has it that it was upon realizing that the site of the famous Spanish Steps in Rome would be desecrated by the opening of a McDonalds in 1986, Italian Carlo Petrini instigated a protest. Together with some of his friends, most of them deeply rooted in Italy's Left, he organized a dramatic sit-in that involved eating traditional Italian pasta. This group subsequently decided to form the action group Arcigola (affiliated with the Italian communist party) to protect local Italian cuisine and Slow Food emerged from this action group 3 years later. In fact, Slow Food's history is somewhat more complex, of course, with its roots already in the counterculture movements of the 1960s and 1970s and the growing global appreciation of, and concern for, Italian culinary culture and heritage (for an overview, see e.g., Andrews, 2008; Chrzan, 2004). Still, the new McDonalds was important in instigating the eventual birth of the Slow Food movement, made official with the signing of the Slow Food Manifesto in Paris in 1989. Petrini became president of this new member-based association and remains so until this day.

From the outset Slow Food has set itself firmly against the threat of the erosion of Italian culinary tradition through the globalization and McDonaldization of society (Ritzer, 2011). That is, from its start in 1989 and under the continuing leadership of Petrini the movement has fought against agricultural industrialization and the resulting rise of homogenous and standardized food which subsequently comes at the expense of not only the taste buds but also of local artisan producers and communities, and thus ultimately reduces the pleasure of food.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64060-6

The initial aim of the Slow Food movement was primarily gastronomic, which is stipulated by its founding manifesto:

> A firm defense of quiet material pleasure is the only way to oppose the universal folly of Fast Life … May suitable doses of guaranteed sensual pleasure and slow, long-lasting enjoyment preserve us from the contagion of the multitude who mistake frenzy for efficiency … Let us rediscover the flavors and savors of regional cooking and banish the degrading effects of Fast Food … That is what real culture is all about: developing taste rather than demeaning it.
> (http://www.slowfood.com/about_us/eng/manifesto.lasso. accessed 10.12.13.)

In its early years, Slow Food focused on gastronomy by (discursively) emphasizing the importance of good taste, artisan production, local and traditional cuisine, and the general importance of pleasure and conviviality (Van Bommel and Spicer, 2011). The movement's tactics to achieve its goals were in these years predominantly local and infrapolitical in nature. That is, Slow Food's activities were largely decentralized around the level of the 'convivia' which formed the backbone of the movement. These regionally embedded groups tried to propagate Slow Food by organizing in civil society a variety of grassroots activities such as markets, discussions, school garden projects, taste sessions, and dinners. Engagement with political elites remained rather limited in the movement's formative years. Still, at a more central level, some early projects started to be developed. Most notably, the first edition of Slow Food's flagship biennial event Salone del Gusto (Hall of Taste) was organized in Turin in 1996. This food fair extravaganza brings together a wide and global variety of products and producers adhering to the Slow Food tradition and by 2012 attracted over 220 000 visitors. At the same time, the Ark of Taste was introduced, which is a catalog of gastronomic products "aimed at safeguarding and promoting small-scale fine food purveyors who are threatened by extinction," according to the Ark of Taste Manifesto Petrini 2001.

Growth and Change

Around the turn of the twenty-first century, a shift started to take place around Slow Food as it expanded its reach, focus, and activities. Perhaps most notably, the movement extended its initial focus on gastronomy to what has now become known as 'eco-gastronomy' and structured its message around the notion of 'good, clean, and fair' food. Essentially, the gastronomic focus broadened with additional concerns for the environmental and sustainability aspects of food as well as a commitment to social-economic justice, in particular also for developing countries and other vulnerable food producers. The idea behind it is described by Petrini as "simultaneously observing the principles of taste, respect for the environment, and biodiversity" (cited in Sassatelli and Davolio, 2010: p. 210). Whereas the term eco-gastronomy appears vague, it is possibly exactly this degree of ambiguity that provides it with meaning for a broad range of stakeholders such as gourmets, environmental activists, and advocates of social justice. This broadening of the movement's discourse not only expanded its appeal, it also added a political layer to food that went beyond merely enjoying it. That is, "a gastronome is someone who combines environmental concern with the pursuit of pleasure; an enlightened citizen who will have an expanding knowledge of food in its social and environmental context and an understanding and empathy for the predicaments of the small producer in the era of globalization" (Andrews, 2008: p. 72). In more plain terms, Slow Food's leader argues that "a gourmet who does not think of ecology is stupid, but an ecologist who is not a gourmet is boring" (*The Times*, 4 December 2006).

In terms of Slow Food's actual strategies and tactics, the movement started to combine its initial grassroots activities with more global, political, and centrally coordinated formal activities. For instance, The Ark of Taste was expanded with an operational arm in the form of the Presidia, which started in 1999. Through this initiative, spanning all continents, Slow Food experts search for products or production techniques at the risk of extinction. Relevant experts, producers, technicians, and institutions form a working group once a suitable end-product or processing method has been found. Whereas the exact strategies vary according to project and product, the Presidia revolve around the desire to promote small-scale artisan products and producers, stabilize traditional production techniques, establish stringent production standards, and guarantee a viable future for the food products as well as their regions and ecosystems, all within the confinements of the Slow Food philosophy by combining economic, ecological, social, and cultural considerations.

In 2004, the Terra Madre project was inaugurated. This landmark project aimed to develop an international network of food communities consisting of producers, farmers, consumers, academics, activists, chefs, and local community members and thus created opportunities to form a network of exchange around food that matched Slow Food's idea of eco-gastronomy and the 'good, clean, and fair' ideals. This integrated notion of food communities blurs the boundaries between producers and consumers, with the latter often being labeled co-producer, highlighting the important role of the consumer in the outlook of (global) food chains. Terra Madre is a good example of the politicization of Slow Food, with a considerable number of Terra Madre's projects involving developing countries. At the same time, it shows the movement's increasing globalization. In short, "Slow Food was now an aspiring global political movement which involved producers as well as consumers in its work, and was able to develop a distinctive position on globalization. Its concepts – Good, Clean and Fair, became the organizing principles for this new 'virtuous' globalization" (Andrews, 2008: p. 48). Highlighting its small-scale, sustainable, and local characteristics, Terra Madre was presented by the Slow Food movement as an alternative to more conventional foodways. In particular, Terra Madre resists the latter's prevailing production methods and consumption habits and the resulting degrading environmental and socio-economic effects on the planet and communities.

In addition to the influential Terra Madre project, the first years of the twenty-first century also witnessed the introduction of more central and formalized initiatives such as the opening of Slow Food's University for Gastronomic Science in 2004. Furthermore, the Foundation for Biodiversity started in 2003 and in 2008 instigated a formalized network of farmer's markets following the Slow Food philosophy under the banner

of the Earth Markets project. On a global scale, a range of Terra Madre events and regional Slow Food fairs start to appear from 2005 onward. Slow Food spin-offs dedicated to Cheese (2001) and Fish (2009) emerged under the banner of the Foundation for Biodiversity. A noteworthy example of the more global outreach of the movement, in particular toward the 'Global South' is the start of the '1000 Gardens in Africa' project in 2010. This practical initiative aims to extend Slow Food's long-lasting focus on school gardens by establishing school, community, or family gardens in Africa. The initiative focuses on creating new, or further developing existing, food gardens. The aim is not just to grow traditional and local produce in a sustainable matter, but also to strengthen community relations, agricultural knowledge, and farmer autonomy.

The movement also starts to engage more directly with political elites than before. For instance, its approach is marked by various political involvements with organizations such as the WTO, UN, World Social Forum, EU, and various national governments and NGOs. The internal structure of the movement has grown more complex while political campaigns and collaborations with elites were taking off. At the same time, however, activities at the local convivia level oftentimes remained less political and more embedded in the gastronomy discourse (Sassatelli and Davolio, 2010). Overall, Slow Food went through "…a rapid cultural change, which led to settlements of the organization's structure, new mass media strategies and, most of all, a growing range of activities and institutions to dialogue with. SF broadened its mission from the developed to the developing countries, from consumption to production, from dish to soil and environment" (Sassatelli and Davolio, 2010: p. 210).

In short, the focus, reach, and range of Slow Food's actions grew strongly in between its inception in 1989 and the present. We discuss in more detail the three aforementioned cross-cutting themes that mark the development of Slow Food.

From Gastronomy to Eco-Gastronomy

A first notable development that arises from the history of Slow Food is the transition from a dining club for gourmets primarily relying on local grassroots activities, to a broader movement initiating global political campaigns and attracting gastronomes, environmentalists, and social justice activists. The problem Slow Food faced was that although it attracted a respectable group of enthusiasts, the demand for Slow Food based primarily on gastronomic issues did not sufficiently resonate with a broader audience. This reliance on gastronomy and pleasure also gave Slow Food a stigma of an elitist club for middle-class gourmets rather than a broad movement trying to change the way people more generally feed themselves (see e.g., Andrews, 2008; Donati, 2005; Sassatelli and Davolio, 2010). Thus, it was of key importance to expand Slow Food's appeal while at the same time make sure not to alienate the loyal, and mainly local, early supporters. Many movements face difficulties in balancing these local grassroots level activities with more formal and globally oriented strategies for a broader appeal. In order to maintain coordination and control, it is common for growing organizations that start at the grassroots level to become more formalized, institutionalized, or hierarchical once they grow (Michels, 1958). This potential disconnect between an appeal based on local, informal grassroots activities and a broader more global and formal approach has been remarked upon in the case of Slow Food as well (Chrzan, 2004). Van Bommel and Spicer (2011) have labeled this balancing act of broadening the movement as Slow Food's attempt to balance a 'strategy of autonomy' with a 'strategy of engagement'.

In addition to the range of strategies and activities discussed, and in accordance with previous studies on social movements more generally (e.g., Laclau, 2005; Weber et al., 2008), Slow Food actively also sought to develop a common language with broad appeal. This became known as eco-gastronomy. After 2000, Slow Food tapped into broadly popular discourses situated around biodiversity, fair trade, sustainability, and social justice, while simultaneously preserving its initial focus on gastronomical aspects such as taste, pleasure, local, and artisan food. Interestingly enough, rather than the Slow Food message getting lost and confused in this potpourri of signifiers it arguably got stronger. Where other studies have warned for the threat of the erosion of the movement's identity (Melucci, 1996), it seems that Slow Food has managed to build its case around a central concept (eco-gastronomy) that is abstract and ambiguous enough to attract a broad range of enthusiasts while at the same time maintaining a coherent identity for the movement as a whole. Overall, it can be argued that Slow Food has been able to appeal "to different types of people in very different circumstances. …It seemed to have the ear of restaurateurs, farmers and policy makers, while retaining a radical and principled position sufficient to capture the imagination of anti-global activists and environmentalists" (Andrews, 2008: pp. vi–vii). Overall, Van Bommel and Spicer (2011) note that Slow Food thus managed to elevate itself by pursuing higher values rather than just enjoying food, and appeals to a broad and diverse mix of actors with various novel messages, strategies, and relationships. Slow Food's broad central concept of 'eco-gastronomy', linked with its continuing focus on 'good, clean, and fair' food enabled a scenario in which the movement offered something of value to a broad constituency.

Against Global Standardization: The Rise of Markets of Authenticity

Recent years have seen a proliferation of alternative markets for the likes of organic, local, sustainable, and fairly traded produce (Reinecke, 2010; Weber et al., 2008). On the one hand, this can be explained in the light of fears over genetically modified foods, widespread use of antibiotics, outbreaks of *Escherichia coli* and mad cow disease, the recent horse meat scandals, and the like. On the other hand, these newly emerging markets can also be seen as a countermovement or alternative to the hegemony of today's globalized food industry based primarily on mass produced and increasingly standardized food. Not without merits, this global system of standardized food has also caused an erosion of the connection between food, its locality, and food producers and consumers (Andrews, 2008; DeSoucey, 2010). As noted by Parkins and Craig (2006: p. 100), "such connectedness – of place, people,

history, culture – constitutes a dynamic set of social relations that is under threat by the chances represented by globalization and its capacity to erase cultural specificities."

In this respect, Slow Food's emphasis on 'terroir' is of particular interest. This concept refers to the importance of the cultural traditions and natural conditions of the local place in which the food is situated and forms a vital aspect of Slow Food's discourse. Interestingly, within today's hegemonic food system the consumer has been increasingly distanced from the importance of place for food, and the same applies to the producer in many cases. Slow Food envisions a future in which consumers and producers once again become closely connected with each other, and the locality of food and its production. This is exemplified by Slow Food's insistence on preferring the word 'co-producer' rather than 'consumer'. This term signifies the active role that consumers play in the cultivation, production, and distribution of food. The Slow Food movement can thus be seen as a form of resistance against forces toward the globalization, standardization, and homogenization of food where it "…has attempted to articulate a politics rooted in local identity, traditions and cultures. Such a position, which suggests a distinctive 'politics of place', questions recent accounts of globalization which sees 'the local' as mainly an appendage to 'the global', driven and shaped by global economies, cultures and trajectories" (Andrews, 2008: p. 129).

With this resistance against the global standardization of food, alternative markets have emerged that tap into a desire for authenticity. For instance, through connecting the production and consumption of food with the significance of culture, tradition, and place, the symbolic function of food is a "marker of identity and community" (DeSoucey, 2010: p. 434). This connection between food and nationally or locally based authentic identities has been labeled by DeSoucey as 'gastronationalism' (2010: pp. 433–434). This concept "signals the use of food production, distribution, and consumption to demarcate and sustain the emotive power of national attachment, as well as the use of nationalist sentiments to produce and market food." Whereas DeSoucey's focus was primarily on national identities, more generally her study hints at a turn toward authenticity, a discourse Slow Food alludes to as well in its many initiatives and communications. That is, rather than problematizing food from a point of reference of politico-ethical (fairness) or politico-economic (safety, prices, transparency), Slow Food's appeal builds on a politico-aesthetic dimension (Sassatelli and Davolio, 2010: pp. 226–227). Thus, the identification with fairness, quality, sustainability, and the like are inextricably linked, if not subordinated, with a right and responsibility toward pleasure, enjoyment, and aesthetic experiences around food. Slow Food typically focuses on rediscovering 'real' and authentic experiences, and on bringing back a human face to the production and consumption of food that provides an antidote against the soul destroying standardization of fast food. Slow Food can thus be seen as part of a broader tendency toward valuing local tradition, 'real' experiences, and authenticity to resist global homogenizing forces (see e.g., Boyle, 2003; Lewis and Bridger, 2001).

Slow Food's authenticity appeals to a sense of identification and attachment, further enhanced by its various processes of mobilization through the multiplication of initiatives, strategies, and activities to broaden the movement (Van Bommel and Spicer, 2011). Prior studies on social movements have shown that a consequence of movements' tendency to "cohere around collective identities and build mobilizing structures is that they often spawn new organizational forms and economic practices that sometimes lead to the creation of new markets or industries" (de Bakker et al., 2013: p. 579). In the case of Slow Food, actual markets are created for endangered products that correspond with the Slow Food philosophy of high quality, local, artisan, sustainable, and fairly traded products. For instance, Chrzan (2004) discusses markets for traditional turkey breeds and raw cheeses in the US that are supported by Slow Food initiatives. In addition, Slow Food Presidia projects have generally created, supported, and improved markets for its products and production techniques, such as Robiola di Roccaverano, a raw milk cheese from Piedmont, Huehuetenango Highland Coffee from Guatemala, and Swedish Jämtland Cellar Matured Goat Cheese (see e.g., Fonte, 2006; Peano and Sottile, 2012).

In addition to these micromarkets for particular products, Slow Food contributes to a reappraisal of the hegemonic food system dominated by corporate capitalism. Slow Food's position of linking the importance of pleasure, place, and conviviality with an acknowledgment of the importance of the environment and social justice gives it ample opportunity to alter the discourse around food. Markets often rely on embedded codes and cultural understandings (Rao et al., 2003; Weber et al., 2008) and movements such as Slow Food "often provide the cultural and material resources needed to create new markets for corporate actors" (de Bakker et al., 2013: p. 581). For instance, continuous taste education around its principles aims for consumers to "use their power of choice to modify market relations, in order to make them fairer and more conducive to a good life for all" (Sassatelli and Davolio, 2010: p. 205). Many initiatives seek to develop alternative food networks, liberate and centralize (small-scale) producers, and extend the alternative consumption movement more generally.

Globalization of the Slow Food Movement

The Slow Food movement has sought to globalize its vision of what an authentic relationship with food and those who produce it might be. For instance, the original concerns of the Slow Food movement which were so deeply rooted in Italian regional food cultures rapidly found resonance throughout Europe, and indeed further afield. Furthermore, some basic organizing models such as the convivium proved to be rapidly replicable and could easily spread. Finally, as the movement spread geographically through both developed and developing nations, centralized co-coordinating functions such as the Terra Madre sprung up which would help to hold this rather dispersed movement together. Whereas the Slow Food movement has a global presence, its members are still predominantly found in the Western world. Still, with its projects and initiatives the movement increasingly reaches out to developing nations as well.

As argued by Van Bommel and Spicer (2011), the Slow Food movement proved to be adept at creating a global

structure through shared discourses (such as eco-gastronomy), practices (such as the convivium), and institutions (such as Terra Madre). These discourses, practices, and institutions were replicable into other sectors such as the design of cities and towns (with the Slow Cities movement), travel (Slow Travel), and journalism (Slow Journalism). The result is a loosely connected 'Slow' movement throughout the world which seeks to address generalized problems with the hyper-industrialization of particular sectors through appeal to ideas and experiences of 'Slowness' (Andrews, 2008; Honore, 2004).

As Slow Food and other aligned movements have shifted from being rather local and limited concerns to becoming a global movement which crosses sectors, a number of challenges have appeared. The first is the ongoing tension between the concerns of local convivium and those of more centralized bodies such as national or international offices (e.g., Chrzan, 2004; Sassatelli and Davolio, 2010). For instance, a local convivium may want to pursue idiosyncratic issues that are out of line or in some cases directly contradictory. Furthermore, local convivia may feel like the creation of centralized offices with full time professionals working in areas such as campaign coordination or fund raising goes against the emphasis on local authenticity. The second major tension between local and global chapters is around issues about commercialism and in particular large international food companies (e.g., Sebastiani et al., 2013; Van Bommel and Spicer, 2011). The Slow Food movement was originally founded as a reaction to mass produced food. Many local convivia remain staunch champions of small local producers. However, to garner the resources necessary to support professional central functions and cross-cutting campaigns, the national or global offices of Slow Food have turned to sponsorships and partnerships with well-known international food brands. Some feel these collaborations to be a contradiction with the focus on small local producers and claim that the movement has been effectively co-opted by large corporations, government agencies, and international NGOs. Defenders of collaborations point out that working alongside these large institutions does not give away concerns for locality and authenticity, but affords the movement an opportunity to increase its impact and reach. The final tension exists between attempts to resist the increasing branding and commodification of foodways on the one hand, and the use of the Slow Food brand to promote the movement.

Many participants in Slow Food see the movement as a way of seeking to overcome the encroachment of commercial brands into the process of preparing and eating food. However, as it has grown, Slow Food itself has used many of the techniques of branding to popularize the movement. This branding has led some to express concerns that Slow Food will simply become an upmarket brand which does not genuinely embody many of the more radical aspects of sustainable food as a social movement (Donati, 2005).

Conclusion

Slow Food is an important movement that has challenged the apparent dominance of 'Fast Food' in many countries throughout the world. It has not only done this by establishing a new market niche and a series of institutions that support small farmers as well as adventurous gourmets, it has also articulated a new set of ideas around food, developed new experiences around how food might be consumed and produced, and perhaps most importantly forged new connections among a range of different parties interested in food. Through doing this, the movement has managed to create an alternative form of food production that is not solely driven by large commercial food producers. This has helped local foodways and traditions to be protected in the face of the ongoing march of industrialized food production.

While the Slow Food movement has been associated with a number of significant successes, it also continues to face new set of tensions. These include the tension between focusing on local foodways while also seeking to globalize the movement; between seeking to be authentic to local concerns and also trying to scale up through working with global institutions; and seeking to challenge commercial logics such as branding and attempts to popularize itself through building a widely recognized image and message. Many of these tensions are precisely the kind faced by similar social movements seeking to cater to the desires for locality and authenticity but at the same time build global connections. The ability to manage these tensions and contradictions will probably be decisive in shaping the future of the movement, and others like it. We therefore think that exploring how movements like Slow Food manage these tensions will prove to be a fruitful and exciting area of research in the future.

Small Group Research, History of

Christian Dayé, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Small group research is a field of empirical research that observes the behavior of groups – and of individuals in groups. These can be natural groups observed in their habitat or 'artificial' groups convened in the laboratory. After blooming in the 1950s, the field receded into the background in both disciplines that originally contributed to it, social psychology and sociology. This contribution discusses the sources relevant to the establishment of the field in the 1940s, introduces three important traditions of small group research, reports some explanations for the field's recession, and presents some newer approaches to the study of small groups.

Introduction

Small group research is a field of empirical research that observes the behavior of groups – and of individuals in groups. These can be natural groups observed in their natural habitat – at the workplace, in the neighborhood, etc. – or 'artificial' groups convened in the laboratory, where for the most part, the group members do not know each other. The field was established in the first decades of the twentieth century, and from the very beginning it attracted researchers from both social psychology and sociology. Its establishment was accompanied with high hopes in the field's impact. It appeared that small group research would be able to develop into a specialty that could span these academic disciplines and guide the further development of both.

The nature of the task at hand requires some deliberate restrictions. Historically, small group research is of Northern American origin. This article is concerned mostly with the history of its early development in Northern America and does not discuss the international diffusion of ideas. For many European countries, however, it holds true that small group research was introduced by two cohorts of scientists. The first cohort consisted of people who emigrated in the course of World War II or earlier due to the Nazi seizure of power and returned to their home countries. The second cohort comprises younger researchers who received post-graduate training in the United States during the 1950s. A second restriction is that conceptual or theoretical differences between approaches must be painted with a big brush. The multitude of different conceptualizations of core notions, like, e.g., the group, and the intricacies that this multitude causes for the theoretical discussion must be neglected (but see Mills, 1967, pp. 10–23, for a thoughtful discussion of various mental models).

A recurrent narrative in the historiography of small group research is that after a first bloom in the 1950s, the field receded into the background. Within the disciplines contributing to it, groups conspicuously – and to most commentators spuriously – moved out of focus. Prior to that, however, small group research was a major player and also a signpost, providing orientation on both intellectual, methodological, and organizational issues to many other lines of research in the Social and Behavioral Sciences (SBS). An important year in the establishment of the field was 1954, when – after a series of influential monographs (especially Bales, 1950; Homans, 1950) and articles emanating from the work at a handful of research centers in the United States – special issues of the *American Sociological Review* (ASR 19 (6), December 1954) and *Sociometry* (17 (2), May 1954) were dedicated to small group research. The latter included an extensive bibliography compiled by Fred L. Strodtbeck and A. Paul Hare (1954), prepared with support by the Ford Foundation's Behavioral Science Division. It documented an increase in magnitude of items on small groups from 0.5 items published per year in the 1890–99 period to 152.5 items in the 1950–53 period. However, these collaborative efforts to create a field that transcends and unifies the various local traditions of small group research, however, were without success; in the 1970s, small group research appeared to be a 'light that failed' (Mullins, 1973, p. 105).

This article is structured as follows: after some remarks on theoretical and methodological sources, three traditions of small group research are introduced and their specificities discussed. The adjacent section reports a variety of arguments put forth in the literature to explain the field's loss of influence after 1970. Further, some contemporary attempts to reestablish small group research as a viable field of research are presented. The concluding remarks attempt an outlook on the future of the field.

Preparing the Ground

Theorizing the Primary Group

Although in many ways related, the history of small group research can be discussed without lengthy references to the conceptual history of the group within SBS or to the theoretical discourse undergirding the research activities. However, some remarks appear appropriate. Social theorizing about the group began earlier, but in the North American scene, Charles H. Cooley's thoughts on primary groups became highly influential and still count as a *locus classicus*. Cooley ([1909]1956, p. 23) defined primary groups as groups "characterized by intimate face-to-face association and coöperation." For the individual, primary groups form the most immediate sources of a socially anchored and therefore more stable worldview. Examples of primary groups include the family, the playgroup of children,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03232-3

the gang, and the neighborhood. They are embedded in society and "to some degree reflect its spirit" (Cooley, 1956, p. 27).

The moral backbone of Cooley's theoretical approach is a concern over the fate of the primary group in modern society. He sees traditional primary groups – mainly the family, but also the neighborhood – challenged by social forces in modern societies. "In our own cities the crowded tenements and the general economic and social confusion have sorely wounded the family and the neighborhood," Cooley ([1909]1956, p. 27) writes, and adds in allusion to social reform efforts that "there is nothing upon which the conscience of the time is more determined than upon restoring them to health." The notion of primary group respectively the perspective on the group as still vital source of social cohesion in modern societies has been influential in several later classic studies of American social science, including *The Polish Peasant in Europe and America* (Thomas and Znaniecki, 1958[1918/1920]), *The American Soldier* (Stouffer, 1949), and *Personal Influence* (Katz and Lazarsfeld, 1955).

Sociometry and Other Early Research on Small Groups

A second source influencing the development of small group research was attempts to systematize the observation of human behavior in groups. Of these, Jacob L. Moreno's sociometry (or sociometrics) probably is the most prominent. While working as a physician in a refugee camp some 20 miles south of Vienna, Austria, during 1916 and 1917, Moreno began to register processes of attraction and rejection within groups. The methodology developed by Moreno in the following decades – mainly after his move to the United States in 1925 – combined a sophisticated psychological theory with a variety of new methods and techniques for observation and analysis, rounded up with a therapeutic thrust.

From the perspective of small group research, the most influential elements of Moreno's system were the methods of observation and analysis. Based on data collected by various means – ranging from direct observation whom a child choses to play with to more elaborate questionnaires – Moreno's *Who Shall Survive?* (1934) introduced visual displays of the relations of attraction, rejection, and indifference within groups (see **Figure 1**). Although less dynamic, with regard to analytical sophistication Moreno's sociometry went beyond the widely acclaimed contemporary studies on norm formation in groups by Muzafer Sherif (1936) or Theodore M. Newcomb (1942). Moreno's attempts to systematically gather data about structures and processes within groups and to display these data visually not only found its continuation in later research on small groups, but also informed social network analysis. However, he came to vigorously oppose the laboratory experiments of both the Lewin and the Bales groups, arguing that it was impossible to capture the dynamics of group life in such artificial, short-term situations (Moreno, 1967, pp. 406–408).

Groups at Work: The Hawthorne Experiments

A third source informing the development of small group research was the Hawthorne experiments, a series of loosely connected tests and experiments at a large factory a few miles west of Chicago, Illinois, that were carried out mainly between 1924 and 1932 (Roethlisberger and Dickson, 2003). Initially designed to investigate the effect of improvements in the working conditions (especially the lighting of the workplace) on the performance of the mainly female workers, the researchers found that what mattered for the productivity of a group was not the objective, presumably improved, conditions. But what then? The interpretation put forth by the team of researchers was that the increase of productivity was caused by the fact that the group was separated from the other workers and treated as something special. "What actually happened was that six individuals became a team and the team gave itself wholeheartedly and spontaneously to cooperation in the experiment. The consequence was that they felt themselves to be participating freely and without afterthought, and were happy in the knowledge that they were working without coercion from above or limitation from below" (Mayo, 1949, p. 64; see also Roethlisberger and Dickson, 2003).

Despite the fact that this interpretation has been fiercely contested ever since (Gillespie, 1991), the Hawthorne experiments received wide acclaim. Probably most important for the trajectory of small group research was that the Hawthorne experiments could be taken as an example of the applicability of social scientific research onto management problems. They established convincingly the relevance of group dynamics research for questions of nonacademic character, be it in business, politics, or the military.

Three Traditions of Small Group Research, 1940s–60s

During its bloom in the late-1940s and 1950s, small group research attracted many talented students. With justifiable restrictions, one can say that three traditions (or schools of thought) shaped the image of the field in these years (Arrow et al., 2000, pp. 11–19; McGrath, 1997). For convenience, these traditions are labeled after universities that played an important part in their consolidation. These are MIT/Michigan, Harvard, and Illinois. Across these traditions, and with

some remarkable exceptions – e.g., the studies of cognitive, dissonance, and informal communication by Festinger et al. (1950, 1956) – most research was carried out in the laboratory and applied experimental designs.

MIT/Michigan

The MIT/Michigan tradition can be traced back to Kurt Lewin's work on group dynamics that he had begun at the University of Iowa's Child Welfare Research Station in the 1930s (Cravens, 1993). Due to the success of his research, Lewin was asked to establish a program on groups at MIT. Lewin followed the call and in 1945 opened the Research Center for Group Dynamics (RCGD) in Cambridge, Massachusetts. After Lewin's premature and unexpected death 2 years later, struggles occurred over the future of the center, and ultimately, a group of RCGD researchers including Dorwin Cartwright, Leon Festinger, John R.P. French, Jr., Ronald Lippit, and Alvin Zander decided to move the center to the University of Michigan, Ann Arbor (http://www.rcgd.isr.umich.edu/history/, accessed 4 February 2014). The process was completed in 1948 and Cartwright became the first director of RCGD at Michigan.

For the small group researchers at Ann Arbor, groups were of interest as 'vehicles for influencing members' (Arrow et al., 2000, pp. 13, 14). They focused on the impact of group dynamics on the individual. Emphasis was put on the forces at work within groups that influenced the opinions, attitudes, or behavior patterns of its members. In the tradition of Ash, Festinger's (1950) work on informal communication started from the assumption that groups exert pressures toward uniformity among its members. These pressures can lead to a change of opinions, beliefs, and attitudes in accordance with the majority, to retention of open discussion of divergent views within the group, or to comparable reactions (see also Festinger et al., 1950, 1956).

Apart from those already mentioned, Kurt Back, Harold H. Kelley, Theodore M. Newcomb, Henry W. Riecken, Stanley Schachter, and John W. Thibaut provided significant contributions to the MIT/Michigan tradition of small group research. Its focus on the impact of groups and group dynamics on the individual members' opinions, beliefs, and attitudes is well documented in one of the tradition's most widely-read publications, *Group Dynamics*, a collection of essays and research articles on small groups edited by Dorwin Cartwright and Alvin Zander (1968, third edition; first edition 1953). How characteristic the emphasis on the impact of group dynamics on the individual was for the MIT/Michigan tradition becomes especially evident if one compares *Group Dynamics* to *Small Groups*, a collection published by researchers from Harvard (Hare et al., 1966; revised edition; first edition 1955).

Harvard

Research in the Harvard tradition did not focus so much on the group's impact on the individual, but rather on the interaction processes occurring within groups. Closer to Moreno's sociometry than the work from the MIT/Michigan tradition, Harvard researchers attempted to measure interaction within groups by quantitative means and to deduce from these measurements some information about the status of the individual group member and of the group as a whole. For instance, Eliot D. Chapple and Carleton S. Coon (1966), in a text included in the aforementioned *Small Groups* (Hare et al., 1966), suggested to test whether or not a group shows equilibrium by observing the rates of interaction between individual members of the group. If these rates remain constant and, after a disturbance, return to a level similar than before, the group has attained equilibrium.

Harvard had been the academic base of the Hawthorne experiments, and some members of its faculty thus were experienced in researching social groups and group effects. This experience obviously spread through many channels. Although its author was only a marginal participant in Harvard's academic life and had received its training at other places, William F. Whyte's study of gangs in Boston's North End, published as *Street Corner Society* in 1943, can in some respect be taken as an early example of the Harvard tradition of small group research. Especially Whyte's serendipitous finding that the results of a bowling evening reflected the status position of the group members shows the interest in group internal status structures that characterizes many works of Harvard affiliates. To the same extent that *Street Corner Society* was a community study (Andersson, 2014), it also was a study on group interaction and performance.

In 1950, two books appeared that consolidated a specific view of small group research at Harvard. The one was George C. Homans's (1950) *The Human Group*, a text that developed a set of core concepts and didactically applied it to the analysis of selected empirical studies, among them some of the Hawthorne experiments, Whyte's *Street Corner Society*, and anthropological studies of 'primitive' and 'modern' communities (e.g., by Bronislaw Malinowski and Raymond Firth respectively by W. Lloyd Warner, Conrad M. Arensberg, and Solon T. Kimball). It has been noted that the adoption of the small group as a core concept for cultural anthropology also happened in the Harvard orbit (Isaac, 2012; Roberts, 1951).

The other, probably even more influential work was Robert F. Bales's (1950) *Interaction Process Analysis*, in which Bales proposed to abstract from the actual content of group interaction and to categorize individual acts according to a predetermined scheme (see **Figure 2**). An act was either a positive reaction (showing solidarity, tension release, or agreement/passive acceptance); an attempted answer; a question, or a negative reaction (showing disagreement/passive rejection, tension, or antagonism). The following years saw Bales' scheme getting integrated into the general social theory developed at Harvard's Department of Social Relations under the leadership of Talcott Parsons (Parsons et al., 1953; especially chapters III and V). Theoretical relations were established with both the pattern variables (Parsons and Shils, 1951) and the then developed understanding of the AGIL scheme.

Apart from those already named, influential contributions came from Edgar F. Borgatta, A. Paul Hare, Fred L. Strodtbeck, and Theodore M. Mills. To all of them, groups were of interest because they "pattern[ed] human interaction" (Arrow et al., 2000, pp. 14–15).

During the 1960s and 1970s, researchers in the Harvard tradition gradually turned away from the aspired heights of a general social theory and became strongly oriented toward social psychology. Considerable effort was dedicated to

CHART. 1. The System of Categories Used in Observation and Their Relation to Major Frames of Reference.

Key:

a. Problems of orientation
b. Problems of evaluation
c. Problems of control
d. Problems of decision
e. Problems of tension-management
f. Problems of integration

Figure 2 Category system of interaction process analysis. Source: Bales, R.F., 1950. A set of categories for the analysis of small group interaction. American Sociological Review 15, 257–263, p. 258.

promoting the formalization and mathematization of small group research (Berger et al., 1962). After complementing the *Interaction Process Analysis* with a method for assessing value orientations (Bales, 1970), Bales, then director of Harvard's Laboratory of Social Relations, developed the Systematic Multiple Level Observation of Groups (SYMLOG; Bales and Cohen, 1979; Bales, 1999), which "provided the benchmark work on group interaction process for decades." (McGrath, 1997, p. 9) (The Laboratory of Social Relations was a research facility set up by Harvard's Provost conterminously with the Social Relations Department in January 1946, but remained formally independent from the latter.)

Illinois

In contrast to the other two, researchers in the Illinois tradition were more concerned with the quality of group performance. They were interested in groups as "vehicles for performing tasks" (Arrow et al., 2000, pp. 15–16). Authors related back to Floyd Allport's theory of social facilitation, i.e., the phenomenon that individuals perform better in the presence of others performing the same task (Allport, 1920). Allport's approach to social psychology was individualistic and "behaviorist in spirit" (Goodwin, 2012, p. 467). Allport "denied the reality of all traditional social objects" and acknowledged only concepts relating to the individual. Any attempt to explain phenomena by emergent properties of a group was derided by him as "the fallacy of the group" (Danziger, 2000, p. 333).

It has been noted that work in the Illinois tradition "is more diffuse" (McGrath, 1997, p. 10); to a lesser degree than the other traditions have there been a coherent body of research or an intellectual program. Apart from the general perspective on what effects group performance, this tradition was not united by a coherent theoretical system. If there is something comparable to the handbook-like publications in the other traditions – *Group Dynamics* for MIT/Michigan, *Small Groups* for Harvard – then this would be Joseph E. McGrath and Irwin Altman's *Small Group Research* (1966). This book, however, was received as a critical assessment of the field rather than as a signpost for orienting further research

projects. Many projects received support from military funds (e.g., Altman and Haythorn, 1965; Carter et al., 1950; Davis and Hornseth, 1967) and, at least to some extent, followed the interests of the patrons. Research dealt with leadership, communication patterns, problem solving, and decision-making in mock juries (e.g., Nagao and Davis, 1980) and other small groups, for instance in sports and the military.

Why Did Small Group Research Recede?

Many observers have commented on the decline of small group research around 1970, and the literature contains a variety of alternative explanations. These range from theoretical to sociological and cultural explanations.

Theoretical Explanations

One explanatory approach puts an emphasis on the theoretical level. For instance, it has been argued that at the time of their decline, the three traditions had reached inbuilt theoretical and methodological limitations. What had been strengths in the process of establishing the tradition had turned into weaknesses, hindering a fruitful development. The input–output approach used both in the MIT/Michigan and in the Illinois tradition and their demand for experimental rigor led to the neglect of natural groups and of the observation of intragroup processes. The fact that Harvard's IPA, on the other hand, was so profoundly integrated in Parsonian social theory made it less flexible and difficult to adapt to research outside this specific blend of structural functionalism (McGrath, 1997, pp. 10–12).

From the supply side, a new paradigm – social cognition – began to dominate the attention space within social psychology around 1970 (North and Fiske, 2012). With its perspective of humans as information processors and its interest in processes of information encoding, storing, and retrieval, social cognition provided an innovative alternative paradigm and thus indirectly contributed to the decline of small group research (see **Figure 3**). As regards sociology, it has been argued that the relevance of the small group has since the 1970s been paradoxically undermined both by the spread of ethnographic observation and the increasing focus on culture. Although in principle, small groups would have given these new perspectives a natural focus, theorizing went beyond the local spheres. Studies of culture researched groups as mirrors of the general culture in a society, and ethnographies – apparently following Geertz's (1973, p. 22) statement that anthropologists do not study villages, they study *in* villages – were more concerned with exploring more general social phenomena than with describing the processes of social organization within groups. In both cases, "the interactional basis of sociality was downplayed. Groups were studied, but they were not theorized" (Fine, 2012, p. 4).

Sociological Explanations

By the end of the 1950s, small group research appeared to be a fractionated field. There was only little intellectual exchange among the clusters that made up the field (Mullins, 1973, pp. 103–128), and small group research lacked the social fundament required to become a successful and stable specialty within SBS. None of those researchers working on small groups successfully synthesized the various findings and concepts into a coherent and innovative theory, and no one stepped in as the field's intellectual and organizational leader. The various handbooks are a quick proof of the field's lack of theoretical focus: the field's disparity was urgently felt by the small group researchers, but they still could not agree on a single theoretical framework. To Mullins (1973, p. 123), the "causes underlying the failure [of small group research] are both social and intellectual." The causes he lists include: (1) the lack of graduate students; (2) social psychology's interstitial status between sociology and psychology; (3) the early loss of a potential intellectual leader (Kurt Lewin) and the failure to find a competent replacement; and (4) the lack

Figure 3 Ngram results for 'small group research, social cognition'. Source: https://books.google.com/ngrams/graph?content=Small+group+research%2Csocial+cognition&year_start=1930&year_end=2000&corpus=15&smoothing=3&share=&direct_url=t1%3B%2CSmall%20group%20research%3B%2Cc0%3B.t1%3B%2Csocial%20cognition%3B%2Cc0, phrase 'small group research, social cognition,' corpus English, years 1930–2008, accessed 12 February 2014. Google Books Ngram Viewer displays a graph showing how often specified phrases have occurred in a corpus of books (e.g., 'British English,' 'English Fiction,' 'French') over the selected years. Clearly not meant to surrogate for a more sophisticated analysis, Ngram Viewer indicates the trajectories of the selected terms or phrases.

of either a program statement or any kind of research direction from a senior, widely respected scholar.

One might also hypothesize whether military and government funding for small group research diminished in the course of the 1960s. With the rise of the computer and the subsequent renaissance of the cybernetic vision of a centralized command and control system, the small group – the team, the squad – might have been seen as becoming less important to military success. However, this hypothesis has not yet been corroborated by sophisticated research.

Cultural Explanations

Several commentators have linked the decline of small group research to cultural implications of the notion of group. I have alluded to some implications above in the passages on Charles H. Cooley. They reverberate many of the connotations of Friedrich Tönnies's distinction between *Gemeinschaft* and *Gesellschaft*, with groups clearly falling on the *Gemeinschaft* side of the dichotomy: they are places for the warm, natural, small, potentially intimate forms of interaction that are so urgently needed to counter the cold, objective, rational, and rationalized forms of interaction in society. On the other hand, society lacks the intimate social control of communities and thus offers the individual more freedom and higher autonomy. Furthermore, groups can lead members onto deviant careers (Park et al., 1984) or could become so important that the 'members' strivings for unanimity override their motivation to realistically appraise alternative courses of action and they engage in groupthink (Janis, 1972). Whether groups are 'a force for good or evil' is a recurrent issue in the history of SBS and philosophy (Levine and Moreland, 2012). And in winding ways, some observers commented, has the fate of small group research been related to the standing of the group within contemporary cultural discourses.

Another form of cultural explanation has been proposed by Ivan D. Steiner, who denied that the decline of group research had something to do with the weakness of the theoretical concept. Rather, he sarcastically proposed, "[i]magine we are viewing a swarm of crawling ants, 99% of whom are moving in the same general direction. We are immediately led to ask what's wrong with those few deviant ants. […] My point is that when society is serene, and only a few wrong-headed deviants disturb our tranquility, we focus our attention on individuals or on large organizations. But when many small segments of society are vying with one another, our attention is drawn to units of an intermediate size. We go where the action is: the prison courtyard, the commune, the assembly line, the committee room, or wherever people assemble and discuss, plot, act, or commiserate. And we find ourselves studying such nebulous things as leadership, cohesion, social facilitation, role systems, and all the rest" (Steiner, 1974, pp. 104–105).

Contemporary Attempts to Revive Small Group Research

While the results presented in **Figure 3** suggest a continuous decrease across the disciplines, studies investigating journal publications conclude that small group research is continued, but moved from social psychology to organizational psychology (Moreland et al., 1994; Sanna and Parks, 1997; see also Stewart et al., 1997). Journals like *Small Group Research* (published since 1970) and *Group Dynamics* (published since 1997) have tried to unify the still scattered field by providing a central publication outlet, but their success in doing so is disputed.

Regardless of its disciplinary location, however, the question has been raised whether small group research requires a new theoretical paradigm in order to regain intellectual attraction and to meet the promises of the field's heyday (Burlingame and Fuhriman, 1997; McGrath, 1997). Out of these discussions emerged an approach that, synthesizing a variety of theoretical elements into a comprehensive paradigm, views groups as complex, adaptive, dynamic systems (Arrow et al., 2000; McGrath et al., 2000): "Rather than simple, groups are complex entities embedded in a hierarchy of levels and characterized by multiple, bidirectional, and nonlinear causal relations. Rather than isolated, groups are intricately embedded within, and have continual mutual adaptation with, a number of embedding contexts. Rather than static, groups are inherently dynamic systems, operating via processes that unfold over time, with those processes dependent both on the group's past history and on its anticipated future. Groups develop as systems over time, and change as a function of changing conditions over time" (McGrath et al., 2000, p. 98).

Another, in many respects complementary, attempt to revive small group research within sociology has been initiated by Gary Alan Fine (especially 2012). Fine conceives of small groups as linking individuals and civil society. They are 'tiny publics' that depend on local cultural understandings – an 'idioculture,' to use Fine's term – that emerge in the life course of the group. Fine studied a broad variety of groups, ranging from Little League baseball teams to fantasy role-playing gamers and mushroom collectors. Fine's sociological approach meets with the emphasis put by psychologists on the dynamic change of groups over time; as a consequence, contemporary small group research appears to be concerned more with natural groups than with adhoc groups in laboratory settings.

Another example of how small group research has recently been used to shape an interesting and innovative argument is Michael P. Farrell's work on collaborative circles. Collaborative circles combine "the dynamics of a friendship group and a work group. At the core is a set of friends who, over a period of time working together, negotiate a shared vision that guides their work" (Farrell, 2001, p. 7). Farrell explores the characteristics of such groups by a series of historical analyses of collaborative circles in art, literature, science, and politics. These analyses show that a set of roles (the leader, the devil's advocate, the peacemaker, the lightning rod, etc.) can be discerned and that usually over time, the members fulfilling these roles change. The development of collaborative circles typically follows a sequence of several stages. After the formative stage, where the core members are introduced to each other, they find themselves united in a rebellion against an authority. In the third stage, the quest stage, they begin to negotiate a new vision that will guide their work in the years to come. This is followed

by a phase of creative work, in which the new vision is explored and developed. In some cases, a fifth phase sees groups take collective action – to organize an exhibition, to found a literary journal, etc. In part because of the efforts and constraints on the individual required for organizing collective action, the sixth phase is typically the separation stage. Finally, group members may come together later in life for a nostalgic reunion stage. Farrell's work is innovative in that it formulates a concept useful for historical analysis that is sophisticatedly anchored in small group research and theorizing. Again, he is concerned with real existing groups, but his data are not derived from participant observation, like e.g., Fine's, but from careful analysis of historical sources – diaries, letters, pamphlets, etc.

Conclusion

A brief outlook on the future of small group research might be appropriate. An increase in scientific concern with small groups will certainly depend on the fruitfulness of the theoretical paradigms available. These must take into account the basic philosophical changes occurring since the 1970s that have left their marks on SBS disciplines, albeit in differing degrees. Although not all aspects of constructivism, postpositivism, poststructuralism, and other lines of critical discourse are relevant, those main points that have entered the mainstream methodological discourse in the SBS should be acknowledged and integrated into the research methodology. The examples introduced in the preceding section do this in at least three ways. They implicitly or explicitly focus on natural groups, emphasize the relevance of time, and construct the relationship between the individual and the group as dynamic phenomena emerging out of interaction. The very concept of membership is problematized. Individuals are not seen as mere group members, but as persons participating in groups. Whether these new theoretical emphases will lead to a rise in the social and infrastructural resources and to the 'critical mass' required to a return of small group research to the forefront of SBS is an open question (Poole et al., 2004).

Abstract

Small states have been the subject of historical enquiry since the writings of Herodotus and Thucydides. Intertwined with the history of empire, the survival or demise of small states has regularly inspired patriotic encomium or tragic lament. Small states threatened by large empires or ambitious neighbors developed numerous survival strategies including alliance, the balance of power, economic specialization, and reliance upon military manliness. All of these were failing by the mid-eighteenth century, leading to a crisis of the small states and the development of new strategies to maintain them in a world increasingly dominated by large commercial empires.

Introduction

Small states have always been threatened by destruction at the hands of more powerful and larger neighbors. That small states were forced in consequence to create survival strategies that might cope with the power imbalance is clear from the earliest histories of Herodotus and Thucydides. The greatness ascribed to the Greek city-states derived in part from a willingness to stand up to the imperial ambitions of Persian Emperors. This pattern has been repeated throughout the recorded history, inspiring glory and causing tragedy in equal measure. The desire for empire and the capacity to establish it can be correlated with the crises of the small states, for whom empire was either inconceivable or undesirable. In Europe more particularly, because of the number of communities across the continent at different times, and because of the lust for empire in the larger states, it might be said that the relationship between small and large states has been still more significant in the shaping of history. The argument can be taken further; the history of modern Europe, with its wars for empire and unions of states in the hope of peaceful coexistence, has concerned the relationship between small and large states. This article identifies some of the strategies frequently adopted by small states in order to survive. It also describes the crisis of the small states in eighteenth-century Europe, after which small states across the globe have found survival more difficult still in the face of large empires with greater political, military, and economic power.

Historical Overview

In the first centuries of the Christian era small states, significantly always likened to faith communities by outsiders, looked to the Roman Empire for their independence. The possibility of maintaining peace by replicating the 'Roman' circumstances of a hegemonic power protecting lesser states was deemed a myth by certain observers in every generation. Yet, however contested, notions of a *pax Romana*, pursued from the inauguration of Augustus as Emperor to the death of Marcus Aurelius, endured into modern times, directly in the form of aspirations to universal monarchy, and indirectly through distinctively Roman ideas about the assimilation of colonies, centering on the introduction of Roman laws and customs to the subject state in return for political privileges. One major fear for small states viewing the history of Rome was that the Romans had tended to protect a state prior to its ultimate subjection. Rome illustrated classic cases of the translation of friendship into dominion, or the transition from a relationship of mutual protection into one of subservience. Overidentification with the culture and politics of a large state was always to be feared. Overreliance upon the economy of a larger neighbor was equally worrying; concentrated economic health was tempting to a large state, which might stimulate its own industries and pay for any aggrandizement by the incorporation of the smaller power.

From the perspective of the small state, trust in its larger neighbor had to be engendered and then maintained. Friendship had to be balanced against the necessary distance associated with continued sovereignty. The tightrope walk of small-state politics always gave way sooner or later, with no small state maintaining its independence in Europe in perpetuity after the fall of Rome. Patterns of policy emerged to prolong the lifespan of small states. Indeed, writers in small states always speculated about the likely future of their state, and this entailed related speculation about the possible futures of larger powers. Comparative study of large states and empires in consequence has tended to be the preserve of authors from small states, as illustrated by such authors as Hugo Grotius, Samuel Pufendorf, Emer de Vattel, and Jean-Charles-Léonard Simonde de Sismondi. These authors recognized that their views were likely to have a large impact upon the policy developed by small-state governments. Several of them were patronized by politicians with a direct interest in shaping policy in a political world of short-term commitments and unforeseen developments.

Prospects for national survival were compounded by uncertainty as to whether neighboring large states were capable of providing genuine security. After the collapse of Rome in the west it was often the case that no major state was capable of aspiring to universal monarchy. Alternatively, universal monarchy was deemed too dangerous a strategy for protecting weaker states, and numerous small states and communities within national sovereignties turned to the Papacy or the Holy Roman Emperor for protection. The history of the Italian maritime republics during the Middle

Ages is instructive here, as the major republics Amalfi, Genoa, Pisa, and Venice, and the lesser maritime powers of Ancona, Gaeta, Molfetta, and Trani, were perpetually involved in securing themselves with the support of shifting coalitions of neighboring or regional powers. The inconstancy of political rule meant that imperial power frequently could not be relied upon to guarantee peace. This was the case in the turbulent fifteenth and sixteenth centuries. Republics such as Genoa then turned to eminent local dynasties such as the Visconti and the Sforza, local princess, French Kings and Emperors for their survival, and in the case of Venice even the Turks. Republics accordingly entered into complicated relationships with larger empires. For example, Ragusa (Dubrovnik) was at various times within the empire of Venice, Hungary, and the Ottomans, while perceiving itself to be an independent republic. As Jeremy Bentham put it in a letter to Prince Adam Czartoryski (21 June 1815), when arguing that his reform proposals were applicable to all kinds of state, "Under the Great Turk was not Ragusa even a republic?"

Complexities of national survival were further compounded by the Reformation, after which small Protestant or Catholic states used the existence of a shared international religion as the basis of preservative offensive or defensive leagues. The impact of Protestant and Catholic leagues of states in international relations after the sixteenth century is a neglected topic in the historiography of political thought. In early modern times more radical sects envisaged communities of the faithful who turned their backs upon contemporary politics at the national level. Small states were often described as churches and the history of certain religious movements to maintain themselves evinced similar concerns and addressed related problems to those experienced by faith communities. One obvious case was that of William Penn and the Quakers. Another was the Pietist Béat Louis de Muralt, who speculated in the 1720s on the relationship between Britain and France for small states before coming to the conclusion that the gradual abandonment of society was the right course for the faithful. In the eighteenth century a variant developed with freemasonry, whose devotees were instructed to accept that the whole world was one great republic, in which every nation was a family, and every particular person a child. For the small communities that continued to exist in state form, alliance continued to be the first means to maintain national independence.

Survival by Alliance

Diplomatic history has today become the central means employed to understand the vicissitudes of the relationship between small states and the monarchical empires of Europe in early modern times. This is right and proper. Contemporaries who were as fascinated by the up and down relationship of major and minor powers looked to the practices of ambassadors, the policy of courts, and the resulting renewal or alteration of established treatises and historic alliances. At times when no power in Europe was seen to be capable of holding the ring, or when the larger states had a manifest and long-term interest in maintaining the *status quo*, sizable states were similarly called upon to play the role of small-state protector in individual cases. Accordingly, much of the history of small states in Europe was concerned with alliances or treaties of peace, either to increase the combined strength of smaller states against larger neighbors, or to shelter within the shadow of an allied empire that was sufficiently powerful not to be overwhelmed by others.

The great means to self-preservation by keeping a general peace was deemed to be the balance of power. From this perspective large states were often described in early modern times as levers within a greater political balance that would ensure peace by pitting states of equal weight against one another. The policy David Hume advised to maintain the balance of power (in an essay of the same name) was alliance with weaker states against the stronger, following the rule pursued by Athens in the war between Thebes and Sparta who 'threw themselves into the lighter scale, and endeavoured to preserve the balance.' Yet as Hume was writing the relative disparity of power between large states meant that the option of treating small states as bulwarks against invasion, or protectorates marking spheres of influence, had come to be questioned. Partly this was due to the nature of war, namely the capacity of able generals to overrun extensive territories with greater speed than in the past. The difficulty of this strategy for the small states of the eighteenth century was twofold. Firstly, the complicated balance of power established by the Treaty of Westphalia (1648) rested on a series of renewable alliances, the breaking of which would have been a direct challenge to the entire system.

Alliance was in consequence a policy undermined by powerful states, so great had the gulf in resources between small and large states become. The most advanced military technology was not seen to be capable of deterring large states' military ambition. Indeed, the solid monopoly by the commercial monarchies of the latest innovations in making war was striking. The bombardment of Genoa with mortars and hotshot from the field guns of the French general Louvois in 1684, simply to apply diplomatic pressure, illustrated the trend. Improvements in the science of siege warfare, exemplified by the career of Sébastien le Prestre de Vauban, made it far easier for monarchies to challenge small states dominated by single cities. As Jean-François Saint-Lambert wrote in the *Encyclopédie* article 'Législateur' (1765), because of their unity of purpose and speed of action, monarchies had an enormous advantage over republics in the pursuit of war.

In alliances between small and large states, smaller states, and especially smaller republics, weaker parties frequently offered economic benefits, such as the stimulation of large-state trade, access to international fairs or markets and, by the eighteenth century, investment in the public debts of large states. When Emperor Frederick Barbarossa considered reviving the empire of Charlemagne and abolished the liberties of the free cities to this end in 1155, he guaranteed the protection of the maritime republics in return for commercial subsidies. In the view of the Scots Jacobite Chevalier Andrew Michael Ramsay, writing in his *Travels of Cyrus* (1730), small states could best survive by commerce, illustrated by the cases of Phoenicia, whose "strength consists in making herself useful and even necessary to all her neighbours," and Tyre, "where commerce is the only support of the state, all the principal citizens are traders; the merchants are the Princes of the republic." The great danger for trading republics was, of course,

the decline of commerce, which "so powerfully operated to the annihilation of the Italian republics as maritime powers."

For some observers the problem was the fluctuating nature of trade itself. The same fate met the 'petty republics of the Hanse towns,' which had 'enriched themselves so greatly by the divisions between Sweden and Denmark' but declined after the union of Calmar. To the eighteenth-century historian, the histories of Crete and Carthage equally revealed that moral, political, and economic dangers were posed for small states when commerce was accompanied by luxury, as was likely to be the case when supplying larger states with trade.

Survival by Virtue

Small states naturally claimed resources of their own to secure their liberty. The major source of self-defense derived from the bonds generated by the very smallness of such communities. Inhabitants identified independence as a supreme political value. Military defense required manliness. Historically, this was most directly associated with the species of small states that called themselves republics. The claim that "virtue and public spirit are the necessary supports of all republican governments," as Montesquieu put it in his *Spirit of the Laws* (1748), was most often cited as the central succor for such states. Every history of a republic that described war against a more powerful enemy employed the trope of martial courage displayed by its citizens because of their patriotic fervor and love of freedom. Ancient examples spoke directly to contemporary times in such histories, with the great examples of the Spartan defense of Greece against Xerxes at Thermopylae and the Athenian destruction of Darius' vast forces at the battle of Marathon finding recent parallels, such as the Dutch independence struggle, which astonished Europe in wars against Spain and then against Louis XIV. In such republics virtue explained their victories and continued survival.

Republican valor embodied manliness. For writers following Livy and Machiavelli, the best way to maintain such a state's independence was to prepare the citizenry for war and plot to create a republican empire, since, as Machiavelli wrote in the second book of his *Discourses*, "Rome made itself strong and powerful by destroying the states round about it, and incorporating strangers within its Citizens." Such claims greatly influenced eighteenth-century thought as John Pocock's *The Machiavellian Moment* abundantly revealed. The sometimes neglected counterclaim, to be found in Pocock's later work, was that all princes ought to protect virtue and that virtue was nowhere the preserve of small states and republics alone. Small states that were not republics equally drew upon the resources of martial virtue and patriotism in their attempts to defend themselves. But what Thomas Paine termed the 'gigantic manliness' associated with republics remained their central means of self-defense and the presumed basis of any success in war.

In *Common Sense* (1776) Thomas Paine wrote, "when republican virtue fails, slavery quickly ensues." Paine was discussing the weakness of Britain, whose constitution was sickly because "monarchy hath poisoned the republic; the crown hath engrossed the commons." Such a state of affairs was contrasted with the virtue demonstrated by the rebellious North American colonists, the modern exemplars of classical republicanism not only because of their rude health and vigor, but also because of the reliance of their economy upon slavery. But, while virtue was seen as a possible basis of a North American Republic, across Europe the leading theme of writers of every persuasion was the natural decline of virtue in republican states. This had been a commonplace in the ancient histories of Polybius, Plutarch, Livy, and Sallust, and was equally prominent in early modern neo-Machiavellian commentary. Virtue was unstable and inconstant, tending to fall prey to the wiles of fortune. Seminal virtue became weak and impaired by inevitable degeneracy through time or the depravity of what John Milton called in *Paradise Lost*, "these latter sinful Ages of the World." An intensely virtuous citizenry could always expect domestic turbulence and warmongering. In the eighteenth century the threat to virtue was greater still because of commerce, the ultimate source of corruption and effeminacy, and the antithesis of the stoic virtues which defined the republican character: steadfastness, loyalty, and self-sacrifice.

The greatest threat, however, to the survival of small republics derived from their military incapacity. By the eighteenth century smaller states could no longer defend themselves against larger states, and especially the commercial monarchies of Britain and France, the empires dominating international politics. In part this was due to the sheer size of monarchical armies and their technological sophistication, which was correlated with the commercial power of a state and its capacity to draw emergency resources from public credit. Although the developing British Empire was seen to be different from that of France, it was equally seen to be potentially devastating for small states. The accusation was leveled that, like all great states, Britain sought to become a universal monarchy. In a related manner it ought to aspire to commercial dominion. In a world in which the relative strength and influence of such states was becoming ever more extensive, no amount of virtue or national patriotism was going to be sufficient for small states to survive intact or untroubled. New ideas were called for to develop means of national survival in the altogether different international political context of the eighteenth century.

Survival by Union

Unions of small states were the long-established solution to problems of monarchical aggrandizement. Unions of states traditionally perceived themselves to be following ancient models, and particularly the union of the tribes that created Israel, and established civil government among the Ancient Hebrews. For much of European history, however, such unions were deemed impractical or failed to be longstanding, the classic case being the union of Calmar between Norway, Sweden, and Denmark (1397), ruptured by the Vasa creation of a separate Swedish monarchy in 1521. The difficulty by the eighteenth century was one of envisaging a union capable of standing against Britain and France, or of adapting itself to a world in which they were the dominant powers. One of the most significant peculiarities of the eighteenth century was the aversion to national unions – such as that of Poland and Saxony or Britain and Hanover – as opposed to large-state

aggrandizement. The Anglo-Scottish union was the great exception, although it was not seen to be a successful model to be imitated by other states until Jacobite challenges had been thwarted. Furthermore, it was seen by its opponents to be another case of a large state extending its empire at the expense of a small state. The message the Anglo-Scottish experiment sent to advocates of union was that uniting small states with larger states, rather than creating conglomerations of small states, might save the weaker sovereignties of Europe, but only at the risk of losing their identity and independence.

The convention by which small states united to form a larger association for defense explained the prosperity of the ancient Greek states, the successful barbarian resistance to Rome between the Rhine and the Danube, and the constancy of republican government in Germany, Holland, and Switzerland. Advocating confederations of states of the same kind, Montesquieu asserted that "the spirit of monarchy is war and enlargement of dominion: peace and moderation is the spirit of a republic." Despite such utterances, Montesquieu was ultimately skeptical about the prospects of a Europe-wide republic or a lasting confederacy of states with different forms of government on the model of the Holy Roman Empire or its microcosm, the Swiss Confederation. Establishment was one difficulty and the maintenance of any confederation another. Such a utopian vision was seen to be the basis of the project for perpetual peace of the Abbé de Saint-Pierre and others.

In the longer term, patriotic and nationalist movements seeking to create more powerful and prominent unitary states, based on shared geographical, cultural, or ethnic identities, sought to challenge the dominion of their larger neighbors, with singular consequences for modern European history. Making small states into large states or into larger unions of states has of course been the preferred solution to the problem of small state weakness in recent times, or at least from the North American founding. Eighteenth-century thought was different because schemes for European or Atlantic unions were then generally described as utopian rather than visionary. With the larger powers seeking to increase national resources in order to undertake global wars against competitor empires, and with a vast number of small and weak sovereignties across Europe, many of which were well known as commercial centers, the temptation for large states to use union as an excuse for the development of empire was too great. National unions involving larger states could rarely be trusted to benefit smaller partners.

The Small-State Crisis of the Eighteenth Century

All authors in the eighteenth century agreed that the small republics could no longer stand alone in war against commercial empires. They had to adapt themselves to the modern lust for trade and empire. In doing so they had to work out means of avoiding collapse in circumstances where Britain or France might seek to conquer them. Alternatively, the small states had to avoid competitors in the east of Europe doing likewise, in the manner of the dismemberment of Poland, which was partitioned between 1772 and 1795 by Prussia, Russia, and the Austrian monarchy. The examples of declining 'sister' states were ceaselessly commented upon as potential futures for the small states and small republics. Poland obsessed Europeans as the great republican monarchy in decline, having too independent, and above all too small, a standing army, monarchs "who had an interest to pursue very different from that of the Republic," and an uncertain division of powers between church and state. The situation of the small communities within the Russian empire was also instructive, because Russia contained so many different forms of state within an absolute monarchy that appeared to function as a federal empire. At the end of the century William Tooke was fascinated by what he called the 'mixed republican monarchy' of 'the Kalmuks and Kirghises'; but the most singular component of the Russian polity he held to be its Sparta – "the military democracy of the Kozaks [Cossacks], the essence and aim of which is war, and even of which we have been witnesses of a corruption, in its denying the other half of the human race all civil and domestic community." Tooke also considered the relationship between religious belief and politics to be significant in Russia, having seen 'the most monstrous polytheism' and 'total unacquaintance with any idea of a supreme intelligence' (*View of the Russian Empire*, 1799). Existence within an absolute monarchical confederation was another possible future for the small republics, but one that none of them recommended or welcomed. Closer to the center of Europe, France and Britain appeared to be perpetually acquiring new territories, with the republic of Genoa ceding Corsica to France in 1764 an apt example, and the British acquisition of Gibraltar in 1713 another.

For some writers there was a natural progression from savagery and barbarism to small dynasties and petty republics, and on to modern monarchy. This was what John Adams was interested in when he wrote that "the checks and balances of republican governments have been in some degree adopted by the courts of princes." Adams was struck by the fact that there were only three innovations in politics that could be said to distinguish ancient and modern times: representations of the people, the separation of the executive and legislative and judicial powers, and the further separation of the legislature itself into branches (*A Defence of the Constitutions of Government of the United States of America*, London, 1787: i–iii).

Adams could not see a great deal of difference between the operation of these principles under monarchies or republics. Such a point of view had led him to be critical of those in North America who drew a sharp distinction between British monarchical traditions and the political ideology of the new republic. When he became the second president of the United States, Adams held that such a fact ought to be in the foreground when adapting the North American federal constitution to a world dominated by European notions of national self-interest. Although Adams remained a republican with respect to North America, the argument that successful small states would do well to model themselves on Britain, or seek the support of empires like Britain in their battles for survival, became more prominent as the nineteenth century progressed.

Small States in the Modern World

After the Congress of Vienna in 1815 the British began to see themselves as the protectors of small states across Europe. As

national confidence increased, reaching a peak during the reign of Victoria, it was increasingly claimed that the small states of Europe could rely upon British arms if larger states attempted to violate their sovereignty. The irony was not lost on international observers that while the British posed as defenders of small states in Europe, they and their European rivals were involved in the extension of their own empires abroad, by colonization or economic dominion. The 'scramble for Africa' is well known, but it had counterparts in every part of the globe during an era of the creation of ever-larger states. If the small states were in decline across Europe in the eighteenth century, the process became global in the nineteenth century.

With regard to Europe, however, the system of alliances established as a result of the Napoleonic Wars required the large states of Europe to go to war if the small states were threatened: this had significant consequences. Sometimes the system of alliances proved sufficiently flexible to prevent war when small states were incorporated into larger empires, as occurred during the processes of German and Italian unification. But the need to defend the small states from attack was equally seen to be a major cause of both the first and second world wars. That they were defending the small and the weak was a claim that could be found on every side in 1914. In other words, as in previous centuries, small states have discovered manifold survival strategies compatible with the existence of global commerce and one or more superpowers in the modern world. At present, nationalist movements in Asia, Africa, and Europe are strong once again. One major difference with previous centuries is the renaissance of ideas about weak or strong federal and confederal unions as a means of preventing the interference of large states. When successful, the small states created have dealt with the some of the problems entailed by their size by adherence to federal unions for trade and the preservation of their sovereignty. At the same time, the existence of such federal unions is held to be destroying national sovereignty. Small states continue to be a political form with a singularly uncertain future in consequence.

Abstract

This article summarizes the vast literature on the concept of Smart City. The concept is first framed in the existing urban economics literature and the ongoing urbanization trends. The article, then, reviews the history of the Smart City concept from its inception, as mostly focusing on information and communication technology endowments as means to foster urban performance, toward the more recent approach based on the concentration of human capital in cities, to, finally, the necessary urban conditions leading to the fast adoption and wise exploitation of e-technologies. Next, the article summarizes the various methodologies and procedures followed in the literature to rank cities according to their degree of smartness. This vast literature is classified in terms of the characteristics pinpointed as major drivers of urban smartness in each work. Finally, the article concludes with a critical review of the Smart City policies drawn by various policy institutions, from the supranational (mainly, EU) to the local administrative level.

Smart Cities in an Open World

Our planet is increasingly turning into an urbanized planet. Cities – or in a more general sense, urban agglomerations – have become the dominant settlement patterns of mankind. Since the year 2007, more than 50% of the world population is living in cities (UNFPA, 2007), with a rapid urbanization rate in Latin America, Africa, and Asia. Consequently, cities tend to become magnets of political and socioeconomic activities, to the extent that modern cities – in particular, megacities – act increasingly as global powerhouses (Neal, 2012). Cities are no longer 'islands of splendid isolation', but global agents with a significant – local and *trans*border – impact. Therefore, in our 'urban century' there is a need to explore and map out the success conditions, strategic profiles, and global impacts of urban agglomerations.

It is noteworthy that cities are not only economic engines, but also part of a *trans*border spatial connectivity constellation. In fact, cities are often part of a functionally and spatially interconnected system of cities. They have to compete and to cooperate in globally interlinked markets to attract clients (business firms, visitors, Foreign Direct Investments (FDIs), knowledge migrants, creative class, etc.). Especially in a knowledge-based economy, skills and innovativeness are often critical success factors for high performing cities. Knowledge intensity, R&D, and innovative minds are a *sine qua non* for a successful modern city (Klaesson et al., 2013).

The increasing scale of cities and their rising economic and political importance also call for efficient governance structures. The traditional hierarchical top–down perspective is being increasingly replaced by participatory, interactive, and self-organizing modes of governance. This new political democratic constellation serves to exploit the development potential of urban agglomerations in a globally competitive and open world. As a consequence, there is a growing need and demand for 'Smart Cities', which are able to cope with both local and global challenges and which are able to employ the available resources (people, energy, land, talent, environment, geographic location) in a way that maximizes overall welfare and sustainable growth. Various important 'grand challenges' (Nijkamp and Kourtit, 2012) inherent in the 'New Urban World' (Kourtit et al., 2014) rise with a view to (stepwise) identification of various multifaceted building blocks that might form altogether a clear measurement and identification of high performing Smart Cities (Nijkamp and Kourtit, 2011). Smart concepts have increasingly become 'en vogue' in recent years. We talk about Smart Cities, smart transport, smart energy, smart grids, smart technology, smart specialization, and smart governance. In many cases, the concept of a Smart City appears to offer an umbrella for an integrated perspective on urban systems characterized by new forms of developing and managing urban technologies and infrastructures that provide efficient and effective solutions to a great many challenges of modern urban life (Kourtit et al., 2013). In particular, such smart solutions serve to enhance the quality of urban services to citizens and business actors, including, e.g., social equity, spatial accessibility, urban sustainability, and socioeconomic vitality.

A wealth of definitions of a 'Smart City' can be found in the literature – sometimes complementary, sometimes contrasting (Deakin, 2010; Torres et al., 2005). In various cases, it is claimed that cities may be smart in the way they exploit the potential of information and communication technologies (ICTs), e.g., for e-government services (Nijkamp and Cohen Blankshtain, 2013), as such services may become vehicles for innovation in cities. Clearly, the measurement of the extent to which ICT offers cities a competitive advantage is fraught with many empirical and methodological problems. In any case, there is a need for operational indicators, which are able to assess differences with respect to a baseline case. The problem of defining a baseline is that not only a clear and measurable urban framework case has to be identified and measured, but also the institutional setting that may be subject to change ('institutional endogeneity'). For instance, the modus operandi of a Triple Helix urban governance model may be influenced by the socioeconomic performance of a city in the previous year

(Etzkowitz and Zhou, 2006). The same holds for the well-known mode 1 and mode 2 research policy configurations based on Gibbons et al. (1994). Kourtit et al. (2013) note the "*tendency to assess Smart City performance not only from an economic perspective but also from an evolutionary, partly noneconomic valuation perspective, in order to suggest solutions for cities to have a competitive edge in a global network economy*" (p. 14). A related concept of Smart Cities can be found in a so-called flagship project 'Smart City' proposed by TNO (2012). This initiative aims to position cities at a competitive global edge in terms of residential and business attractiveness. In this initiative, cities are spatially integrated agents of individual and collective interest, in which information collection, use, and sharing offers an unprecedented value added in terms of quality of life, ecological sustainability, and economic vitality. Smart Cities arise because of intelligent use of digital information, for instance, in domains like human health, mobility, energy use, education, knowledge transfer, and urban governance. The basis of this idea originated from Castells' (1998) contribution on the distinction between 'Space of Places' and 'Space of Flows', next to a 'Space of Information'. All these spaces are integrated in a Smart City. Thus, interfaces of spaces and data are crucial for a Smart City in the TNO conceptualization.

The present article serves to present a concise state-of-the-art overview of the concept of 'Smart Cities', with the aim to provide informed insights into the strength–weakness conditions for 'Smart City' initiatives. The article is organized as follows. First, in Section Definitions and Conceptualization of Smart Cities an overview of the ways the notion of Smart City has been conceptualized and defined will be offered. Next, Section Ranking Procedures for Smart Cities will focus on the different methods used for ranking Smart Cities. Section Policies on Smart Cities will explore the policy implications stemming from the concept of Smart City.

Definitions and Conceptualization of Smart Cities

The profile of a Smart City has, in recent years, become an interesting research topic in urban research and policy (Winters, 2011; Caragliu et al., 2011). It concerns various disciplines, from economics to political science, from smart ecology to smart urban architecture and planning, from smart technological (mainly ICT) development to globalization forces (including international trade). Cities are multifaceted organisms, acting in complex environments, shaped by other urban areas – both neighboring and far away– and by general national and global drivers (Kourtit et al., 2014). This calls for new concepts, which can be difficult to define (Nam and Pardo, 2011), among which the notion of Smart City has recently gained much attention among policy makers, private firms, and researchers. Because of the difficulties in properly defining new urban concepts, it becomes fundamental to narrow the research scope on the concept of Smart City.

Several definitions have emerged over time, each differing from the other in terms of the main 'smart' characteristic deemed as the most relevant. Initial conceptualizations revolved around ICTs as the main pillar around which a city should build its smart pathway. Earlier definitions related to the concept thus include the 'wired city' (Dutton et al., 1987), whereby the focus is on networking the urban space per se and the 'intelligent city' (Komninos, 2002, 2009), which expands this idea by considering also the cognitive element of a digital city and the relationship between individual cognitive skills and the urban information system.

Linking smartness to the availability, development and use of ICT is based on the notion that in order to succeed, cities and urban dwellers must be interconnected. The focus on information technologies and data availability is also related to a policy shift from mainly top–down to increasingly more bottom–up approaches, paving the way for greater importance of citizens' direct participation in the urban governance and their links with city officials. This latter aspect is related to the importance of e-government in the creation of a Smart City (Deakin et al., 2011). This in turn suggests an important role for the human capital component of cities and might also give rise to concerns related to the availability, management, and privacy issues related to 'big data' (Batty, 2012).

This vision of ICT-focused smartness eventually spurred several academic projects and research, not without critiques to the business orientation of this concept. In fact, ICTs have been, from the very inception of this concept, considered at the roots of urban smartness, mostly because of the vast empirical evidence supporting ICT led development (Caragliu, 2013); this attracted the interest of large corporations, aiming at obtaining profits from the interest of urban administrations in such technologies (Vanolo, 2013). This type of critique argues that the Smart City concept would be void of objective content, and would concentrate the attention of citizens and policy makers toward the adoption of ICT technologies, thus ignoring the need of nondigital citizens, or, more importantly, the equal rights of cities that voluntarily choose not to go digital (Hollands, 2008).

Yet, the Smart City concept is not a static idea, and has been recently evolving. Such evolution, which partially tackles these critiques, took place especially in the EU, in relation to the overall sustainability goals of the EU2020 framework, placing more focus on environmental sustainability and clean energy issues. In terms of the conceptualization of Smart City, the focus on environmental issues is incorporated in the concept of 'resilient city' (Newman et al., 2009). This further characterization has also given rise to several studies exploring the need, development, and impact of smart solutions in energy creation and consumption, such as smart meters and smart grids (Clastres, 2011).

The focus on ICT and sustainability in the policy and academic domain are mirrored in the business and consultancy sector, where the interest for the Smart City concept is related to the development of software solutions and applications and management models related to both ICTs and energy. From a purely academic point of view, Smart Cities are often identified in relation to their human capital component and potential (Berry and Glaeser, 2005; Shapiro, 2006; Winters, 2011). The interest on the subject, in the policy, business, and academic worlds, briefly documented above, has given rise to several attempts of providing

a definition of the concept and develop rankings of Smart Cities around the world.

Despite the relevant academic success and the significant investments in Smart City projects at all administrative levels, however, only few works provide a clear-cut definition of what a Smart City really is, in particular extending their characterization beyond the pure technological (viz., ICT-related) content, thus including contextual elements. Because context elements should be expected to explain the success, or failure, of Smart City policies, this article only summarizes four notable definitions (in chronological order) which go truly beyond ICTs as a means to define urban smartness, highlighting the most important elements.

A first comprehensive operational definition of urban smartness is implicitly to be found in Giffinger et al. (2007). Giffinger et al. (2007) provide in fact a classification of European medium-sized cities according to six axes (Smart people, Smart governance, Smart environment, Smart economy, Smart mobility, and Smart living). Their definition reads as follows: "*A Smart City is a city well performing in a forward-looking way in these six characteristics, built on the 'smart' combination of endowments and activities of self-decisive, independent, and aware citizens*" (Giffinger et al., 2007: p. 13).

Caragliu et al. (2011) build on the classification by Giffinger and coauthors, and provide a comprehensive and operational definition of urban smartness. In this case, cities are identified as smart when "*investments in human and social capital and traditional (transport) and modern (ICT) communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance*". This definition presents two main advantages. First, it is inspired by an urban production function approach, whereby urban smartness is defined as a precondition to urban economic performance. A clear distinction between inputs and outputs, previously not encompassed in analogous attempts, suggests that smartness can be seen as an intermediate step toward the goal of smart (viz., sustainable) urban growth. Second, the definition decomposes the concept along six dimensions, which can be individually measured and tested, using data from official statistical sources. Therefore, this definition has been among the first ones to be empirically verified (Caragliu and Del Bo, 2012).

More recently, the interplay between technology and its users has been synthesized in Ratti and Townsend (2011), which simplifies the previous approach by stating that "*Truly smart cities will emerge as inhabitants and their many electronic devices are recruited as real-time sensors of daily life*."

Finally, De Souza (2012) concludes that "*A smart city is livable, resilient, sustainable, and designed through open and collaborative governance*." This last definition builds a bridge between previous works focusing on ICTs and context conditions as the main ingredients of urban smartness, and paves the way for future evolutions toward the resilient city.

Clearly, operational definitions must be clarified before measuring and/or ranking cities in terms of smartness, as well as before committing financial resources to policies aiming at stimulating the success of such cities, as they can be a starting point for empirical assessments of the degree of 'smartness' of cities and for sound and valuable policy evaluation exercises.

Ranking Procedures for Smart Cities

The discussion on Smart Cities seems to concentrate nowadays on two major issues:

1. Is a given city a Smart City? This is an empirical research question that can only be answered if clear threshold conditions for the smartness of a city are specified. In reality, we often face no binary conditions, but grades of smartness (e.g., on a scale from 1 to 10).
2. Which city is the smartest city? This question calls for clear benchmark principles, so that a ranking – or even rating – of the various alternative cities under consideration can be obtained. This research question runs parallel to the related question of which city is the most sustainable or most ecofriendly.

The assessment of the degree of smartness of cities leading to a ranking of Smart Cities calls for an operational methodology. The methodological toolbox for a quantitative underpinning of such rankings can be manifold. Examples include spider diagrams to map out the differences or indicators among the set of Smart Cities considered; multivariate analysis to reduce the multidimensional nature of the underlying database, in order to be able to select the key indicators for Smart City achievements; unweighted summation techniques to arrive at an unambiguous ranking order of Smart Cities; multicriteria models to arrive at an unambiguous ranking or rating of the various cities concerned; and, finally, data envelopment analysis to trace the relative ranking of Smart Cites in terms of their relative performance.

Clearly, there may also be a ranking of appropriate benchmark techniques that can be employed to identify the relative profile and performance of a set of Smart Cities. Such a comparative analysis may also be instrumental for Smart City policies. This will be further discussed in Section Policies on Smart Cities.

The study undertaken by the Center of Regional Science, Vienna (Giffinger et al., 2007) aims to rank medium-sized European cities according to their degree of 'smartness'. A Smart City refers here to cities with ICT-oriented industries, including advanced business parks, higher education facilities, and e-government amenities. These aspects are summarized in six characteristic building blocks, as described in the previous section: Smart economy, Smart people, Smart governance, Smart mobility, Smart environment, and Smart living. Each of these six building blocks is decomposed into subcharacteristics. For example, Smart economy (or competitiveness) is subdivided into seven indicators: innovative spirit, entrepreneurship, economic image and trademarks, productivity, flexibility of labor market, international embeddedness, and ability to transform (Rudolf et al., 2010). Through a standardized scoring approach the various European cities in the sample – 70 in total – can then be ranked according to their degree of smartness, with Luxembourg at the top and Ruse on the other end of the spectrum. More fundamental arguments on this type of city ranking methods can be found in Begg (1999).

A more general review of the notion of a Smart City and its positioning in the urban planning literature can be found in Caragliu et al. (2011) (Section Definitions and

Conceptualization of Smart Cities above). The fundamental components of this definition of urban smartness are the widespread use of a networked infrastructure, the city's emphasis on a business-led urban development, its socially including urban residents in the provision of public services, the central role given to high-tech and creative industries, the important role played by social and relational capital, and, finally, social and environmental sustainability as a strategic core orientation for the city.

Kourtit et al. (2013) provide a followup on this ranking, especially from a dynamic competence point of view. They suggest that the environmental and climate neutral capabilities and resources, along with advanced infrastructure, smart logistic systems, smart energy use, accessibility and connectivity, and other spatial facilities, are decisive for the relatively strong competitive position of Smart Cities in the complex force field of urban dynamics. However, much room is left for further empirical verifications and rankings of Smart Cities, in particular linking theory to practice and policy making, with the lenses of the definitions and conceptualizations discussed in Section Definitions and Conceptualization of Smart Cities.

Policies on Smart Cities

Born in the policy context, the notion of Smart City has attracted vast attention both from policy makers and private companies. While the focus of policy makers, due to the original nature of the Smart City concept as ICT-driven, is still on communication technologies, nowadays attention is increasingly being paid to the human and social capital concepts and to environmental sustainability as means of complementing ICT infrastructure. In fact, the only addition of ICT infrastructure to a city cannot per se suffice to determine its success: the broader context conditions need to be conducive to the full adoption, understanding, and wise exploitation of these resources.

Because the concept of Smart City has been mostly studied in a European context, European Union institutions have been focusing most intensely on Smart Cities strategies. Several EU- and local authorities-funded research projects have provided the rationale for the need for policies stimulating urban smartness. Funding bodies and EU institutions include Urbact, Interreg, CORDIS, the European Investment Bank, and the European Commission (the Web sites of the listed projects are added in the Reference list). Other international institutions have also provided evidence about the need for an ICT-driven form of development; these include, among many examples, the Intelligent Community Forum, the Organisation for Economic Co-operation and Development (OECD) and EUROSTAT, whose Oslo Manual (EUROSTAT, 2005) discusses the importance of innovation in ICT industries as a growth driver.

Practically, the largest commitment of public money toward Smart City policies has been made by the European Commission with the Smart Cities and Communities European Innovation Partnership (EC, 2012), which implied so far a total investment of 450 million euros (Falk, 2012). At lower administrative levels, numerous cities, mostly located in the EU28, embarked on Smart Cities projects (to name a few, Amsterdam, Aarhus, Genoa, Lyon, Málaga, Santander, Southampton, and Turin). Notable nonEU examples include Dubai and Singapore.

Along these projects, a relevant role is also played by large ICT companies, with a clear target to diffuse ICT technologies, sensors, advanced heating systems, traffic control devices, etc., to as many urban areas as possible. Multinational Companies with relevant Smart City projects include IBM, Cisco, Hitachi, and Siemens.

Thus, it can be argued that Smart City projects can be classified on the basis of the promoting industry and of the level of aggregation. The most relevant stakeholder is probably the public sector. At the supranational level, EU institutions have committed relevant funds for applied research for the identification of the potential impacts of Smart City policies. This goes under the umbrella of the Smart Cities and Communities European Innovation Partnership.

At the local level, local (city) authorities focused on funding local initiatives targeting ICT infrastructure and the improvement of the context conditions leading to the skilful adoption of such technologies. Such local policies include, among countless recent examples, *Amsterdam Smart City*, Southampton's *Smartcities Card*, and *Smart Santander*. In these cities, funds have been invested, and cooperation efforts put in place, with the aim to improve modern ICT infrastructure and enhance its skilful application by teaching people how to make the best use of it, and show citizens and entrepreneurs what the future of their cities will look like.

Clearly, such government-led efforts could not be carried out without resorting to large corporations willing to invest in Smart City technologies. Multinational companies such as IBM, Cisco, Siemens, and Hitachi have initiated dedicated lines of business for the development of technologies aiming at reducing environmental pollution, fostering a more efficient energy and waste management, and, in general, making the organization of cities easier and more effective.

The public and private sectors do not necessarily interact in a smooth way. In fact, the interplay between the public sector's need for advanced technologies, looking for a better and wiser management of complex urban systems (Caragliu et al., 2011), and the private sector's push for the diffusion and penetration of smart technologies, has also drawn criticism from the academia (Vanolo, 2013; Hollands, 2008).

So far, theoretical definitions of urban smartness have been only partially translated into practical policy making: academic definitions of the concept of Smart City tend, in fact, to be heavily cited within the academic world, and, by the same token, policies tend to avoid making reference to academic definitions. In other words, definitions of urban smartness seem so far to have been only partially shared by academics and practitioners. Besides, the private sector is characterized by socially inefficient incentives toward the diffusion of smart ICT technologies for urban mobility, and traffic and waste management. Externalities emerge in fact in the use of publicly funded ICT infrastructure, whose cost is born only partially by the individual taxpayer, and whose use makes individual citizens and firms more productive. Thus, the present state-of-the-art of the literature on Smart Cities suggests a clear need for bridging theory and practice in shaping sound Smart City policies. Theories and policies related to Smart Cities are still

in their infancy, and call for further research in order to strengthen the concept's theoretical architecture and to shape sound policy making.

Abstract

Adam Smith is often said to have been the founder of the science of economics and the father of liberalism in the sphere of economics. In fact he was neither. He lived at a turning point in western economic and political history, one that was littered with disruptive developments. He came up with a masterful synthesis of the economic knowledge of his period and emphasized both the relative autonomy of these phenomena and their importance in terms of generating wealth from, and in the interests of, everyone. Nevertheless, Smith never denied the moral foundation of economic behavior.

> Political economy, considered as a branch of the science of a statesman or legislator, proposes two distinct objects: first to provide a plentiful revenue of subsistence for the people, or more properly to enable them to provide such a revenue or subsistence for themselves; and secondly, to supply the state or commonwealth with a revenue sufficient for the public services.
>
> Adam Smith, *The Wealth of Nations* Book IV, Introduction (Smith, 1999(1776): Intro. p. 5)

A Scottish Thinker

Adam Smith was born in January 1723 in the small town of Kirkcaldy on the coast of Scotland a few miles north of Edinburgh. He matriculated at Glasgow University in November 1737. Glasgow at the time was a commercial harbor in which tobacco and wool were traded, and ships built. Edinburgh was an important center of intellectual activities. As a 17-year old he went to Oxford University to study philosophy and literature for 6 years. In 1751 he became professor of literature at Glasgow University where from 1753 he took the chair in moral philosophy. He achieved a great scholarly repute giving lectures on ethics, rhetoric, literary style, justice, security and 'cheapness or plenty.' Already then, he was addressing the issue of political economy in his lectures. In connection with his lectures on ethics he wrote his first seminal work: *The Theory of Moral Sentiments*. A work which, besides its great erudition and originality, was written in a clear language, which Edmund Burke was to describe as 'rather painting than writing.' Its publication in 1759 led to Smith's appointment as tutor to the third Duke of Buccleuch. In this capacity he spent nearly 3 years in France from 1764 to 1767 conversing with many leading French intellectuals, among whom were D'Alembert, D'Holbach, Dupont, Helvetius, Morellet, Necker, Quesnay, Turgot, and Voltaire. Back to Scotland in 1767, Smith dedicated most of his time writing the work for which he became well known worldwide: *The Wealth of Nations*. It was published in 1776, soon translated in many languages and had an impact on the politics of Nations. For the rest of his life, Smith was mainly busy with new editions of his work and high charges that he held. He died in 1790 in Kirkcaldy at the age of 67.

Founder of Economics

Adam Smith was one of the earliest thinkers to suggest that laws on a par with those reigning in the world of physics could be applied to economic systems. Indeed he is often said to have been the founder of the science of economics and the father of liberalism in the sphere of economics. In fact he was neither. He lived at a turning point in western economic and political history, one that was littered with disruptive developments. He came up with a masterful synthesis of the economic knowledge of his period and emphasized both the relative autonomy of these phenomena and their importance in terms of generating wealth from and in the interests of everyone. Nevertheless, Smith never denied the moral foundation of economic behavior. The fact that his work inspired after his death a massive body of economic theory, more abstract than ever existed before, should not conceal the fact that Adam Smith himself was more a philosopher than an economist as his inquiries into economics were much more motivated by an understanding of human nature than by an intention to develop an autonomous science. Far from developing a reductionist view of social relations, Adam Smith provided an elaborated critique of a short-sighted political approach to economic life.

While the economy was strongly influenced by market exchange in Adam Smith's time, that part of economic life, which was under the political sway of aristocrats, was still rooted in appropriations, donations, and privileges. The fact that political power was in the hands of the aristocrats, whereas wealth stemmed largely from a market economy, was a major source of tension at the time. In England, which was then the world's dominant power, technical inventions flourished, the population was growing, agriculture had been restructured, social classes were evolving, and there were lively debates on political and ethical matters. European governments were interested mainly in power, war, money, and agricultural production since these could bolster their position. Because of his interest in exchange and in production and consumption of whatever type, Adam Smith brought in a more rational way of contributing to the wealth of nations and a more modern understanding of what society is and how it works. His declared ambition was to enable people to provide themselves

with adequate resources and in so doing to generate a surplus sufficient to finance public services.

In order to do this, Adam Smith analyzed the mechanisms of national growth on the basis of fundamental factors and concepts. Some of these ideas came from his own reading of earlier scholars. For instance, his distinction between productive and unproductive work comes from the physiocrats; the idea that capital is part of a stock that can be allocated to productive work presupposes the idea of stock as put forward by the mercantilists. At any rate, Adam Smith stated that there are three factors of production: land, labor, and capital. He defined wealth to be purchasing power and believed there to be a link between the wealth of each individual and the wealth of everyone in society. He distinguished exchange value from use value, i.e., the usefulness of an object. He recognized that the growth of capital enables division of labor to be augmented and its productivity to be increased. He brought to the fore that which contributes to an increase in wages and demand but also contributes to a decline in profits. He criticized outdated ideas on wealth and political economy. Thus, merely accumulating precious metals and colonies does not, *ipso facto*, increase a nation's wealth. Labor is the real source of wealth. He believed that it is the market which should be the center of attention rather than money or land. Restricting flows of goods and particularly import quotas gives rise to an unsatisfactory allocation of capital and inadequate division of labor. State aid to exporters can have negative effects. Smith was also interested in return on investments made by the state.

The fame of Adam Smith's work spread rapidly. This was largely due to the winds of change mentioned above, but also because of the American war of independence (1775–83), which persuaded England, as well as many other countries, to change their views with respect to international relations and wealth. Adam Smith put forward solutions to the problems of his time. And, since his ideas influenced the political economy of the world's dominant power they quickly became widespread. Smith founded the so-called classical school of economics on his critique of the mercantilist ideas of the previous century and it was this which, in the next century, from David Ricardo to Jean-Baptiste Say, had a big influence on Karl Marx. Marx was later to place great emphasis on the self-regulating nature of the new, capitalist economy, which, in Smith's time, was still embryonic and utopian. Furthermore, in addition to highlighting the fact that workers were not fully paid for their labor, along with describing (in the Book V of *The Wealth of Nations*) the negative impact of the division of labor on workers' mental health, Smith was also the first to put forward an economic definition of social classes and to define profit in relationship to the input of capital. It is worth pointing out, nevertheless, that, as far as he was concerned, the key conflict was not between workers and capitalists, but rather between those who were in favor of competition and those who wanted government protectionism and the establishment of monopolies. It should also be borne in mind that Smith basically ignored the question of money in his search for fundamental economic laws; it was only after the 1929 Great Depression and John Maynard Keynes' work that political economics took a serious interest in monetary aspects once again. Nevertheless, Smith's dynamic systems approach has continued to influence generations of economists and sociologists. This is still very much the case, 200 years after the publication of *The Wealth of Nations*; an example being the French *Regulation School* (Michel Aglietta, Robert Boyer).

Ideological Twists

Just like those of Karl Marx (1818–83) a century later, Adam Smith's ideas have been hijacked for ideological purposes and reduced to the role of rabble-rousing slogans that are a long way from the powerful insights imbued in the original ideas. The facts that the original analyses were rooted in a given historical context with a well thought-through conceptual system are ignored. By taking things out of context not only do the words and quotations lose their meaning, but also they become useless in terms of understanding evolving social phenomena. And yet Smith has provided us with a remarkable synthesis of the economic and political ideas of his time and proposed a radically different roadmap for the future development of our society. Contrary to the currently prevalent ideological caricature, Adam Smith was not an advocate of laissez-faire capitalism who believed that the wealth stemming from the growth of capital would eventually trickle down to those who it exploited. He was a theoretician of the relationships between markets and society who shed light on how an understanding of economic phenomena could contribute to a fresh understanding of government, society and the relationship between them. He drew attention to the importance of productive work, everyday consumption, and national trade. Smith, a moral philosopher facing the intellectual challenges of his time, helped not only to found economics as the science of wealth, but also sociology as the science of social bonds. In doing this, Adam Smith actually helped to bring into existence both the market as it is today and the state. It is unhelpful, though, to reduce his contribution to being merely a champion of laissez-faire.

An Industrial Revolution in Embryo

At the time when Adam Smith was reflecting on the evolution of society, the industrial revolution was in its infancy. In 1769 James Watt patented his steam engine, two years later Richard Arkwight set up the first cotton-spinning mill, and the *spinning jenny* and the *mule jenny* appeared in 1770 and 1779, all increasing productivity while requiring adaptation to new and restrictive collective work systems. Despite these changes, the industrial revolution had still not really taken off by Smith's death in 1790. There were still far more household servants than factory workers and craftsmen, and most work was still carried out at home and without the help of machines. Nevertheless those changes were significant in some parts of the population. They altered human relations, calorific intake, time disciplines, patterns of sociability, and family possessions; they resulted in gains in productivity and social satisfaction (Bayly, 2005: p. 49). Today's economic historians call our attention to the fact that an 'industrious revolution' had begun in the late seventeenth century of a process of household-based resource

reallocation that increased both the supply of marketed commodities and labor, and the demand for market-supplied goods (Vries, 1994). Although Smith himself did not foresee the industrial revolution at all, he did notice this 'industrious' revolution. Smith drew attention to the importance of the national product and the internal market; he saw that if one took the trouble to enhance these, they could become sources of wealth for the whole of society.

A New Conception of Society

In Adam Smith's epoch systems of production, trade and the priorities of rulers were quite unlike those we see today. Notwithstanding this, people had already begun to reinterpret the world in a quite different way from that of a few centuries earlier. A slow disintegration of the traditional social order and its *weltanschauung* had already begun in the thirteenth century, while, from the sixteenth century onwards, the religious foundations, in which political ideas were rooted, had begun to creak ever more loudly. This disintegration accelerated in the seventeenth century, when the possibility of a lay society really came to the fore. As Max Weber (1864–1920) was to put it later, there was a 'disenchantment'; society came to rely only on itself; this was a new way of understanding politics, and it now included economics.

It was not only a 'disenchantment' of society, it was also a new conception of history and of the competition between the concern for salvation and the need for knowledge. Humankind was no longer only to rely on divine grace; a better life was believed achievable by the exertion of its own powers. The scientific revolution provided mankind with a new mastery over the conditions of its existence and suggested that the production of knowledge is cumulative and irreversible; thus the idea of progress was emerging. Also emerging, in Smith's time, was a new understanding of the relations between the elements and the whole of a system: the self-correcting procedure of scientific discovery allowed the scientific enterprise as a whole to flourish in spite of the constant revision and even rejection of particular findings.

Back in 1615 Antoyne de Montchrétien in his *Traité de l'économie politique* (Montchrétien, 1889(1615)) had argued that what matters the most for a community's fate is neither its religious devotion guided by its clergymen nor the courage and military skills of its noblemen, but the occupation of the common people. What people produce and consume, how they organize their work, how clever the artisans and the merchants are – this is what affects the most the general good. Montchrestien was not the first to make that point. Barthélemy de Laffemas who was the commercial advisor of the French king Henri IV has already pointed that out in 1606. Precisely this idea will be at the core of Adam Smith's argumentation 170 years later.

What Smith set down was in fact the conclusion to a lengthy period of philosophical debate concerning the institutions and the regulation of society, once freed from references to the holy writ. A fresh reality had appeared, one requiring a new language, a new way of speaking and seeing, and different behaviors. The main problem of political philosophy at this time was how to come to terms with an autonomous society with no reference to an overarching external authority. What is it that binds a society together? How long has it been so bound? How can we make sure that it will continue as a coherent whole? By the eighteenth century the main issue was to understand how society was *regulated* and to ensure that it had a simple and solid basis.

A New Relation between Morals and Politics

The problem of morals had been handed down from a religious *weltanschauung*, but, from Machiavelli (*The Prince 1513*) onwards, it was looked at in a nonreligious context. In this new, lay context it was no longer a question of teaching mankind what *must* be done with reference to the next world, but rather to understand what man actually is and what can be done in this world with men as they actually are. From the seventeenth century onwards the idea spread that the social contract and the workings of society should be studied *on the basis of natural human emotions and not despite them*. In order to endow society with a solid and universally acceptable foundation, it was therefore necessary to develop a science of *human emotions* on the lines of the *science of reason*, as exhibited by mathematics. This implied casting doubt on all forms of power that are not based on reason.

Adam Smith is part of the philosophical tradition within which morality and politics are inextricably intermingled. Politics was increasingly perceived to be the art of managing human emotions. When he was 30 years of age, Smith became chairman of the moral philosophy department at Glasgow University. Six years later, in 1759 he published his *Theory of Moral Sentiments*. It was his interest in what can drive moral behavior that led Smith to lay greater stress on the economy than on politics. In *An Inquiry into the Nature and Causes of the Wealth of Nations*, published in 1776, he portrayed society as no longer being basically a political system, but rather an economic system within which markets can play a beneficial role. Though the markets of which he speaks did not actually yet exist he sensed that the world was changing. Bolstered by the advancement of scientific explanation during the century of Galileo, it was henceforth possible to envisage a change from mere submission to the dominant authorities to a scientific approach to the mechanisms of society. Market forces, essential to society, could actually be studied and encouraged in order to enable wealth within a nation to grow. That they could be studied and managed indicates that we are a long way from the laissez-faire ideology to which his theory of markets has been reduced. The idea of free markets carried with it the desire for self-regulation of civil society and thus a certain ideal of autonomy. Actually Smith's work contributed to and participated in the elaboration of a market-driven utopia as a principle of social organization in a period of widespread disruption; although the power of the church was on the wane, it was still fairly unthinkable to question the growing authority of sovereign rulers. In the reflections stemming from the bulk of political philosophy, ordinary people's consumption was not yet of interest. In the hands of Louis XIV, consumption was but a political instrument,

a method of ruling. However, political power had developed in different ways in different countries where the transcendental idea of society was no longer extant.

The Birth of Nations

When Smith was born, France was still an absolute monarchy: the French state was not only very firmly in control throughout the country but also garnered its force and its income from this control. This absolute monarchy had systematically eliminated all intermediary groups, all traditional communities, extended families, religious orders, and guilds in a bid to establish a direct link between each individual and the state. Consequently, France as a whole had become a dynamic tool applied to the construction of a monarchical system. Political economics is concerned more with the confirmation of this grip on an area while political philosophy leans more toward a critique of despotism. In Great Britain the state was not so omnipotent and not so ubiquitous. A constitutional monarchy was set up in 1688 and John Locke's (1632–1704) ideas became widespread. Tolls were practically unknown. The inland communication network was less developed. The French state lived off taxes on internal trade, whereas the English state derived its revenue from taxes on wool, which was a key commodity in foreign trade.

In France the state actively sought to expand its internal market in its own interest. By the close of the fourteenth century, a royal permit was required to set up fairs and markets. In Great Britain prior to Smith's period domestic trade was not taxed very much and tolls were almost unknown. Road and fluvial networks were less well developed than in France. That being said, in Smith's time foreign trade was expanding without changing its nature while domestic trade was undergoing radical change in both countries. In summary, a new form of social relationships appeared, including relationships between people, their relationships with geographical space, with the powers that be, and with what was perceived to be possible; these new relationships took on a different shape, notably in terms of the ways in which, from the fourteenth century onwards, the decomposition of the political form of the empire varied spatially. In fact the nation-state and free markets, which appeared were basically a new way of representing and structuring social space.

The Relation between Nation-State and Market

Adam Smith's work fitted into the dynamics of the development of political economics, the subject of which was precisely this relationship between the nation-state and free markets, between economic activity and political action.

For a while those who were trying to understand this relationship looked at the economy basically from the point of view of those in power. Adam Smith looked at the generation of wealth in general, i.e., abstractly and not merely in terms of the sovereign's interest. Before him, not only did those who looked at the economy see it in terms of the sovereign's benefit, but those who looked at trade saw it only from the traders' standpoint. With Adam Smith, however, it was the nation as a whole that became key: *civil society*, as it became known, took on both economic and political importance. And one of the main reasons why this concept took root in Great Britain was of course that civil society was more advanced there. Indeed in France, the state continued to be a system of power and administration, whereas in England the state saw itself more as providing and guaranteeing the rule of law. It was this that enabled James Steuart (1713–80) in particular, in his *Inquiry*, to envisage political economy on the basis of a relatively autonomous civil society and a state which does not merely govern. His fellow countryman Adam Smith went further. He refused to limit himself to the study of what may be useful to lawmakers or statesmen and sought to understand and be of use to civil society in and of itself. (See the introduction to Book IV in *Wealth of Nations*). By doing this Smith became the first person to dilute the political concept of nation in the economic concept of the market. In his view, free markets and not the state were the number-one factor in generating wealth, whereas the distinction between the domestic and the political economy was no longer fundamental. The science of wealth looks at all those phenomena which, in a modern society wherein the rule of law obtains, are worthy of attention if one wishes to improve the material standard of living of everyone in the society.

As Rosanvallon has shown (Rosanvallon, 1999), Smith's conception of markets enabled certain issues to be analyzed in a radically new way. The first inversion of perspective was to enable relationships between nations to be perceived as being complementary rather than antinomic. Whereas *rapports de force* (power relations) between nations are only to the benefit of the dominant power, trade between nations can be beneficial to all. Political wars, when redefined in terms of competitive trading, become a force for peace and, rather than dilapidating wealth, this force contributes to wealth creation for all. The second major shift concerns that which binds society together. Whereas both Hobbes and Rousseau – despite their opposing ideas – see the social contract in terms of submission (to the sovereign for the former and to the general good for the latter), Smith's free market ideas enable one to conceive of a society without a central node and without the phenomenon of submission. Each individual institutes and perpetuates society in his everyday relationships with others. Rising above the lawmakers, the markets regulate not only the relationships between goods, but also a substantial proportion of the relationships among people. Having sought to run government on the basis of absolute truth with the rationale of the sovereign lord as the inevitable starting point, henceforth, it would be necessary to take into account the rational behavior of those who are governed.

It is no longer a question – as in Hobbes and Rousseau – of knowing how to find in the origins of society the legal setup that would keep power in check from the outset. Henceforth we are dealing with a society that works autonomously and one where subordination phenomena contribute to social development. As Michel Foucault commented, starting from Smith on, "the problem is simply how to regulate and limit power within a society in which subordination is already at work. It is

in this way that the question which has obsessed practically all political thought from the end of the 18th century to the present arises, that is to say, the question of the relations between civil society and the state" (Foucault, 2008(2004): p. 309; Foucault, 2004: p. 312).

A Liberal Stance

In fact Smith, just like Marx later on, made, above all, a synthesis of a substantial amount of the research and thinking that was available to him at the time. He did not invent the labor theory of value nor the theory of the division of labor. This latter concept appears not only in a number of publications at the beginning of the seventeenth century, but also in the works of Plato. Many thinkers prior to Smith had already defended free trade and delved into the price mechanisms for allocating scarce resources and regulating trade. Mandeville and Hume had already split the economy off from moral considerations and were both of the opinion that it is through their own interest that people can be ruled. Steuart had already pointed out that markets are not a substitute for the social contract, they are the driving force heralding democracy (Rosanvallon, 1999: p. 49).

Notwithstanding the foregoing, before Smith no one had presented what has come to be called the *liberal doctrine* in such a systematic and well-argued way. It is not merely a question of the *invisible hand*, which, for some of his lesser followers, constitutes his conception of free markets. Smith only used this expression on three occasions in three separate publications and, as Emma Rothschild has shown, in a fairly ironic manner (Rothschild, 2002: Chapter 5). Michaël Biziou also showed that rather than to a benevolent providence, what Smith refers to in these occasions is the fact that individual actions can have unwanted consequences which can be beneficial as well as harmful to society (Biziou, 2003). In fact, long before Hegel, Adam Smith was the first person to understand civil society in economic terms. According to him, it is the economic link between production and consumption in free markets that binds society together. And 'the market' is not limited to a certain type of exchange; according to Smith it is society as a whole that is organized on an exchange basis. The division of labor for Smith plays a fundamental role in the transformation of society and the consumer becomes a citizen of a secular society. Smith was the first to emphasize the need to create a veritable market society because the market of which he spoke did not yet exist in his time. He believed it was necessary to understand its advantages and to facilitate its emergence. He had a rather negative opinion of the merchants vindicated in the fact that, when exempt from state control, merchants' behavior often tended to be harmful to the common good. Nevertheless, Smith was against the mercantilists, who believed that the state represented the interests of everyone, considered traders to be unproductive, and thought that farm produce was more important than all other activities and trade. But Adam Smith was not an advocate of laissez-faire. Nor was he of the opinion that everything depends on free markets. Not only should the state provide a system of justice and infrastructure (roads, bridges, ports, and so on), it should also promote science as "*the great antidote to the poison of enthusiasm and superstition*" (*Wealth of Nations*, vol. II, Book V, Chapter 1). Smith was also in favor of political regulation to encourage movements of goods trade and to resist market related social problems, such as the exploitation of apprentices. We should bear in mind that the factories and working classes analyzed by Marx did not appear until later.

A Scientific Point of View

In fact the abstract system studied and favored by Smith must be distinguished from what was later to be dubbed capitalism, the main feature of which was not the general good, which Smith aspired to, but rather the accumulation of *abstract capital*. Smith took inspiration from the physical sciences to study the systems of relationships. Inspired by Newtonian physics, he sought to break down and rebuild the mechanisms of society on the basis of a minimum number of assumptions, possibly in the hope of identifying a law similar to the law of universal gravitational attraction formulated by Newton (1643–1727). Smith looked for causal relationships and often ruled out numerous background factors in the hope of perceiving fundamental relationships more clearly. Perhaps he thought he would discover some simple principle of organization, especially since he – as his master and friend Hobbes – had great faith in mother nature and believed, as did many of his contemporaries, that mankind would be wise to pay attention to her. He simplified even more so because the market system turned out to be so complex that understanding all its mechanisms in detail would be beyond the intellectual grasp of legislators. Here again, however, Smith did not reduce society to a mere mechanism. What he did rather was to identify factors that were likely to contribute to the *wealth of nations* relegating other factors to the background noise as it were. The workings of the state in his time did not appear to him to contribute much to the *wealth of nations*. In line with the principles developed by the mercantilists and the physiocrats in the interests of sovereign rulers who were no longer subject to religious ethics, state action usually consisted of encouraging any activity that would fill their coffers with money. Smith had far greater confidence in social relationships that work in such a way that everyone gains through them. This was particularly the case since he was one of those in this period of history who thought that man has a natural propensity to help others.

Self, the Other, and the Social

Smith's well-known theory of self-regulating supply and demand first arises in the moral propensity that he describes in his *Theory of Moral Sentiments*, which was published 20 years earlier in 1756. Many people are indeed astonished that Smith should have arrived at economics from his starting point in moral philosophy. However, according to Dupuy, Smith believed that moral philosophy and economics are one and the same science (Dupuy, 1992: p. 101). Smith's ponderings on moral issues took place in a climate of reflection that was very much present in his Scottish entourage. It had appeared as

a reaction against thinkers such as Hobbes who saw only cynicism and selfishness in man. Smith's own *maitre a penser* in Glasgow, Francis Hutcheson (1654–1746), taught that man had an innate tendency to universal goodwill but was torn between its egoistic and altruistic instincts. Another thinker who influenced Smith, David Hume (1711–76), believed that moral judgments are not rooted in reason but in feelings. Smith's original contribution was to lay stress on *self-love*, and to merge self-interest and self-love. He says "Sympathy, therefore, does not arise so much from the view of the passion, as from that of the situation which excites it" (Smith, 2000(1759): p. 7). Smith emphasizes the importance of our imagination. While we obviously never leave our own minds and bodies, we are constantly imagining ourselves in the place of others. He writes "We sometimes feel for another, a passion of which he himself seems to be altogether incapable; because, when we put ourselves in his case, that passion arises in our breast from the imagination, though it does not in his from the reality" (Smith, 2000(1759): p. 7). Thus sympathy does not arise from *selfishness*. In Smith's view, *self-love* is informed by the recognition of others. To put it another way, the Smithian subject needs his fellow men in order to forge an identity. This foreshadows Hegel (1770–1831) who was later to state that one's identity depends on recognition by others.

A Forerunner

Adam Smith prefigures René Girard's and Jacques Lacan's Theory of Desire, since he emphasizes the wish for the approval of others in the feelings and emotions that motivate one's acts (Bouchet, 2011). This is a most modern conception of human relationships, where each individual is supposed to put her- or himself in someone else's situation, imagining that the other does the same. And it is true that, in a market context, each individual will take actions, be a spectator, and also be both a producer and a consumer. One might almost say that the Smithian *Theory of Moral Sentiments* heralds the rise of sociology and foreshadows some of Durkheim's analyses in his *Elementary Forms of the Religious Life* (1912). Thus we see that Smith may be considered to be a precursor of sociology because he gives priority to social relationships. In fact he takes it for granted that it is human relationships that mediate their relationships to objects. (Notwithstanding this, he does consider exchange to be a natural tendency and not a social category.) Smith may also be viewed as an anti-utilitarian, since he shows that men think they are pursuing utility whereas in fact what they seek is recognition and admiration. Here we are far from the caricature of *homo economicus* that has been disseminated by a form of economic liberalism that no longer has much in common with Smithian sociology.

Adam Smith also foreshadowed the theoreticians of the consumer society. He pointed out that we do not need a great deal to meet our basic needs. Anything beyond that is used mainly to attract attention – gain respect or attain recognition others would later say – through *sympathy*. Smith thus conceives of *sympathy* (which has much to do with empathy) as being the foundation of any evaluation of how we feel. In his *Theory of Moral Sentiments* Part I, Section I, Chapter 3, Smith writes "Upon all occasions, his own sentiments are the standards and measures by which he judges of mine" (Smith, 2000(1759): p. 15). And a few pages later he says "Every faculty in one man is the measure by which he judge of the like faculty in another" (Smith, 2000(1759): p. 18).

Thus, according to Smith, empathy encourages men to reconcile themselves with one another, but one cannot ignore moral values. Free markets cannot work without certain moral virtues, notably prudence and justice. Without these, the economic exchanges and the markets of Smiths' scheme, cannot develop. Sympathy and benevolence also play a role. On another tack, Smith believed that the same mechanisms that can contribute to the wealth of nations and – as he saw it – to social cohesion can also give rise to their corruption. It is odd, therefore, that some still portray Adam Smith as an apostle preaching that the market is a superior substitute for politics and morals. It is also worthwhile highlighting that the economic system, which Adam Smith put forward as a utopian model in his time is not ubiquitous. It is a system founded on a certain type of market, a certain type of mutual confidence and self-perception, and a certain type of property and division of labor. Again, in Smith's day, the economy of the Western world was an aristocratic one based on gifts and privilege. Examples of other societies that have experienced different modes of economic development, other types of bond between material and spiritual phenomena, and people abound: ancient Greece, China, India, and Japan, inter alia. Today we can say that the capitalist system could not be studied until it had come into existence, but that the gradual way in which interest and conceptual analysis in and of it has grown has contributed strongly to its expansion and its continued existence. Smith was as much an analyst as a utopian. He was a social theorist who gave the most powerful theoretical boost to the modern economy and who still continues to have a major influence on the way in which people today perceive their relationships with the world about them and among themselves. Social scientist keep going back to his work to find inspiration for an understanding of social change. Thus, it has recently been used by the sociologist Giovanni Arrighi to analyze the origins and dynamics of China's recent extraordinary rise and the ongoing shift of the epicenter of the global economy from North America to East Asia (Arrighi, 2007).

Abstract

Cigarette smoking is the leading behavioral cause of preventable, premature death, killing 6 million people annually. This article describes the burden of smoking, explains how epidemiological science unearthed the principal tobacco-related disease connections, and summarizes the causes of tobacco consumption. The article then describes the efforts of social and behavioral scientists to improve the effectiveness of smoking cessation techniques and contribute to the formulation of effective tobacco control programs and policies.

Introduction

Worldwide, 1 billion people smoke cigarettes, with nearly 80% of smokers living in low- and middle-income countries (LMICs). According to the World Health Organization (WHO), 6 million people die annually as a consequence. Smoking is the leading behavioral cause of preventable, premature death throughout the world, responsible for one of every 10 adult deaths. If current trends persist, smoking will claim as many as one billion lives during the twenty-first century (WHO, 2012).

The causes of this pandemic of avoidable disease and death are a complex web of physiological, psychological, social, marketing, and policy factors. Social and behavioral scientists of all disciplinary stripes have contributed to identifying and disentangling these factors, although no single model has yet adequately characterized the interactions of these determinants. Social and behavioral scientists have also elucidated important mechanisms by which both private sector and governmental intervention can discourage the initiation of smoking and encourage quitting.

After a brief description of the burden of smoking and how epidemiological science unearthed the principal tobacco-related disease connections, the causes of tobacco consumption are summarized. The efforts of social and behavioral scientists to improve the ability of smokers to quit smoking are then described, including better theoretical characterization of the determinants of success in quitting and the development of more effective cessation interventions. Next examined is how social and behavioral scientists have analyzed the effects of selected, important tobacco control measures and thereby contributed to the formulation and implementation of tobacco control programs and policies. Finally, the future contribution of the social and behavioral sciences to dealing with a potentially even greater cataclysmic crisis in world health during the remainder of the twenty-first century is considered.

Traditional methods for the prevention of 'youth smoking,' such as school health education and the enforcement of minimum age-of-purchase laws, are only touched upon, due in part to limited scientific understanding of how initiation can be effectively discouraged and also because it is covered elsewhere (Lantz et al., 2000; US Department of Health and Human Services, 2012; *see* Substance Abuse in Adolescents, Prevention of; Health Promotion in Schools).

Cigarette Smoking and Disease: Making the Connection

In the major industrialized nations, smoking causes from a sixth to a fifth of all mortality. The two major smoking-related causes of death are lung cancer and coronary heart disease (CHD). In the United States, epidemiologists estimate that smoking accounts for close to 90% of all lung cancer deaths, with lung cancer the leading cancer cause of death in both men and women. Smoking is credited with better than a fifth of CHD deaths. In addition, smoking causes four-fifths of all chronic obstructive pulmonary disease mortality and just under a fifth of all stroke deaths (US Department of Health and Human Services, 2004). The exposure of nonsmokers to environmental tobacco smoke is also a substantial cause of disease and death (US Department of Health and Human Services, 2006).

Mortality attributable to smoking is rising rapidly in LMICs, reflecting their large but more recent adoption of smoking. WHO estimates that nearly 80% of the world's smokers now reside in LMICs. By 2030, WHO projects that four-fifths of smoking-produced death and disease will occur in LMICs (WHO, 2012).

Although the health hazards of tobacco smoking have been suspected for centuries, serious interest is a twentieth-century phenomenon, coincident with the advent of cigarette smoking. Prior to the twentieth century, tobacco was smoked primarily in pipes and cigars, chewed, or used nasally as snuff. Harsh tobaccos made deep inhalation of tobacco smoke difficult. Tobacco probably exacted a modest toll through the nineteenth century.

In the United States, four factors combined in the early twentieth century to make cigarette smoking the most popular, and lethal, form of tobacco consumption. Perfection of the Bonsack cigarette rolling machine in 1884 introduced relatively inexpensive and neater cigarettes to the market. Discovery of the American blend of tobaccos (combining more flavorful tobaccos from Turkey and Egypt with milder American tobaccos) made deep inhalation of cigarette smoke feasible. The development and marketing of Camel cigarettes in 1913, the first American blend cigarette, introduced this new-generation product to the American public with an advertising campaign often credited with inaugurating modern advertising. Finally, cigarettes were included in soldiers' rations

during World War I, permitting soldiers a quick and convenient battlefield tobacco break. Considered effeminate and unattractive prior to World War I, cigarette smoking came home from it a 'manly' behavior. Since then, cigarette smoking has dominated all other forms of tobacco use by far in the United States and in most countries of the world (Brandt, 2007; Proctor, 2011).

Lung cancer was virtually unknown at the beginning of the twentieth century. By 1930, it had become the sixth leading cause of cancer death in men in the United States. Less than a quarter of a century later, lung cancer surpassed colorectal cancer to become the leading cause of male cancer death. It achieved the same status among American women in the mid-1980s, surpassing breast cancer (US Department of Health and Human Services, 2004).

The rapidly growing rate of lung cancer in the early decades of the century spurred a number of epidemiologists and laboratory scientists to begin investigating the relationship between smoking and cancer. Wynder and Graham (1950) published a now classic retrospective epidemiologic analysis that strongly linked the behavior to the disease. Throughout the decade, a series of articles documented similar findings from major prospective (cohort) mortality studies in the United States and the United Kingdom. Scientific groups in both countries soon thereafter published seminal public health documents indicating smoking as the major cause of lung cancer and a cause of many other diseases (Royal College of Physicians of London, 1962; US Public Health Service, 1964).

By the end of the twentieth century, approximately 70 000 studies in English alone associated cigarette smoking with a wide variety of malignant neoplasms and cardiovascular and pulmonary diseases, as well as numerous other disorders. The modern plague of tobacco-produced disease is now rapidly metastasizing – both figuratively and literally – to the world's poorer nations, the result, in part, of increasing affluence and western image-making.

The Causes of Smoking

Smoking affords users a very mild 'high' and addresses a number of often seemingly competing physical and psychological needs – for relaxation or stimulation, distraction or concentration, for example. The crucial element in the sustained use of cigarettes is the addictiveness of nicotine in tobacco smoke. Once addicted, as most regular smokers are, smoking serves the physiological purpose of avoiding nicotine withdrawal. Nicotine affects brain receptors in much the same manner as other addictive substances, and withdrawal shares many of the same unpleasant characteristics (US Department of Health and Human Services, 2004).

In most countries, smoking is initiated during the teen and even preteen years. At the time of initiation, new smokers typically do not appreciate the nature of addiction, much less the addictiveness of nicotine. Further, they tend to be short-sighted and unconcerned about potential distant adverse health consequences (US Department of Health and Human Services, 2012). The combination translates into a large pool of new smokers who have adopted the behavior and become addicted, without considering either the danger or the addictiveness of smoking; a situation that most will come to regret.

The physical effects of nicotine notwithstanding, history teaches that virtually all drug use is socially conditioned; tobacco smoking is no exception. The use of tobacco in the Americas prior to the arrival of Europeans demonstrates this vividly. Although tobacco played a prominent role in most native societies, in some, tobacco smoking was restricted exclusively to the shaman, who used it for medicinal and religious purposes. In other societies, tobacco smoking anointed the official nonsectarian functions of tribal leaders (such as the famous 'peace pipe'). In still others, nearly all males smoked tobacco frequently, for personal and social reasons (Goodman, 1993).

In contemporary society, the initiation of cigarette smoking is often viewed as a rite of passage to adulthood. In many poorer societies, smoking is seen as a symbol of affluence. In virtually all cases, smoking results from role modeling of parents, prominent celebrities, or youthful peers.

Many tobacco control advocates attribute much of smoking's holding power to sophisticated tobacco industry marketing campaigns. In the United States alone, the industry spends billions of dollars per year on advertising and other forms of marketing. The industry insists that the purpose of its advertising is solely to vie for shares of the existing market of adult smokers, a claim greeted with derision by the 'public health' community. With US smokers exhibiting strong brand loyalty and two companies controlling over 70% of the US market, marketing directed at brand switching (or its defensive analog, maintaining brand loyalty) would appear to be a relatively fruitless investment. Tobacco control advocates thus believe that much of the industry's marketing effort is directed toward attracting new smokers, primarily children but also groups of first- and second-generation American adults not yet fully acculturated into American society (e.g., Hispanic females, among whom there is very low prevalence of smoking).

Similarly, the introduction of aggressive Western cigarette marketing into Asian, Eastern European, and African countries has been attacked by the public health community as spurring the growth of smoking among children and other traditionally nonsmoking segments of society (e.g., Asian females). In many of these countries, cigarette advertising was nonexistent or restricted to modest use of print media prior to the introduction of advertising by the major multinational tobacco companies. Before the dissolution of the Soviet Union, there was virtually no advertising of the state-produced cigarettes in the Eastern European countries. That ended with a flourish when multinational tobacco companies entered the newly liberated economies and, in some instances, took over cigarette production from the inefficient state-run enterprises. In Japan, the state tobacco monopoly had never bothered to advertise on television prior to the entry of the multinationals. In short order, competition from the advertising of Western cigarette brands led to cigarettes becoming the second most advertised product on Japanese television. In Africa, the advertising media portray smoking as the indulgence of the much–admired affluent set, with billboards in desperately

poor villages depicting high-society Africans smoking and smiling in convivial social settings.

Although many tobacco control advocates find advertising a convenient villain to attack, widespread smoking has often preceded formal marketing. Tobacco smoking spread like wildfire through much of Europe in the sixteenth and seventeenth centuries. Similarly, male smoking rates in Russia and the Eastern European countries were very high prior to the fall of Communism and the advent of modern cigarette marketing. The effects of advertising are further examined in Section Analysis of the Effects of Tobacco Control Policies.

The Art and Science of Smoking Cessation

In countries in which the hazards of smoking have been well publicized, surveys find that most smokers would like to quit and most have made at least one serious 'quit attempt'; yet relatively few of those who try to quit succeed in any given attempt. In the United States, for example, approximately 70% of smokers report that they want to stop and as many as half the smokers try to quit each year. Yet only 2.5% succeed in quitting each year. Combined with persistent cessation efforts by many smokers, this modest quit rate has created a population in the US in which there are as many former smokers as current smokers. Thus, in the aggregate, quitting has significantly reduced the toll of smoking but the toll remains stubbornly high due to the difficulty of quitting. Concerns about that difficulty are exacerbated by data indicating that adult smoking prevalence in many nations leveled off during much of the past decade – in the United States it did not change at all from 2004 to 2009 and fell only slightly during the next 2 years – and it has even increased in a few countries that previously had managed to reduce prevalence significantly. For example, in Singapore, smoking prevalence rose from 12.6 to 14.3% from 2004 to 2010.

Although most former smokers quit without the aid of formal programs or products (Chapman and MacKenzie, 2010), the widespread desire to quit, paired with its difficulty, has created a small but thriving market for interventions that increase the odds of quitting smoking. Formal cessation interventions range from the distribution of how-to-quit booklets, to mass media cessation campaigns, to individual- and group-counseling programs, to self-administered nicotine replacement therapy products, to use of cessation pharmaceuticals combined with clinical counseling. The efficacy of interventions ranges from sustained quit rates of about 5–7% for the most general and least resource-intensive interventions (e.g., generic cessation booklets) to 30% or more for the most resource-intensive programs that combine sophisticated counseling with the use of pharmaceuticals (Fiore et al., 2008).

Over the years, behavioral scientists have helped refine smoking cessation techniques by evaluating interventions and developing theory applicable to smoking cessation. Preeminent in the domain of theory have been models that characterize how smokers progress, through a series of stages, to contemplate, attempt, and eventually succeed or fail in quitting, with cessation maintenance also examined (Prochaska and DiClemente, 1983). Relating cessation advice to smokers' stages of readiness to change constitutes one way of 'tailoring' cessation messages. Another involves tying cessation advice to the specific motivations and concerns of individual smokers trying to quit. For example, consider a smoker motivated to quit primarily by the high cost of smoking but also concerned about gaining weight. Armed with this knowledge, a cessation counselor can develop specific information on the financial savings the smoker can expect once he or she quits, while suggesting specific strategies to avoid weight gain (or to deal with it if it occurs).

Tailored cessation messages have the obvious virtue of meeting the idiosyncratic needs of individual smokers. In the absence of computer technology, however, they would entail the substantial cost of collecting information on the individual's needs and concerns and then developing individualized (tailored) cessation advice for each person. Computers, however, permit simple and inexpensive collection and translation of information into tailored cessation materials, such as individualized advice booklets and calendars with specific daily advice and reminders (Strecher, 1999). Online programs can provide instant tailored suggestions to help people quit smoking. The concept of tailoring holds great potential to enhance quit rates both in individual counseling situations and in low-cost online programs.

Social and behavioral scientists have also played a central role in defining appropriate medical treatment of smokers. The US Public Health Service's clinical guideline for smoking cessation was produced by an expert committee, including social and behavioral scientists who had worked on smoking cessation as service providers, developers or evaluators of interventions (Fiore et al., 2008). The guideline urges physicians to regularly counsel their smoking patients about the implications of the behavior and encourage them to quit. It concludes that a highly effective cessation approach involves physician counseling to quit, supplemented with use of cessation pharmaceuticals and maintenance advice through follow-up contacts. A cost-effectiveness analysis of an early version of the guideline added economics to the social sciences contributing to understanding optimal smoking cessation therapy (Cromwell et al., 1997).

Despite substantial improvements in the efficacy of cessation treatments, in any given year only a small fraction of the smokers who say they want to quit succeed in doing so; and only a small fraction of these have employed professional or programmatic assistance. As such, in any short-run period of time, the contribution of smoking cessation interventions to reduce the health toll of smoking is modest at best. This source of frustration has led a subset of smoking cessation professionals to explore methods of achieving 'harm reduction' that does not depend on smokers completely overcoming addiction to nicotine. Harm reduction techniques range from helping smokers to reduce their daily consumption of cigarettes to encouraging consideration of the long-term use of lower-risk nicotine-delivery devices, such as nicotine 'gum' or the patch or even low-nitrosamine smokeless tobacco products. Though fraught with problems, harm reduction may be an idea whose time has come (Zeller et al., 2009).

Analysis of the Effects of Tobacco Control Policies

Another way to grapple with the toll created by smoking is to develop policies that discourage the initiation or continuation of smoking or restrict it to areas in which it will not impose risk on nonsmokers (Warner, 2006). Social and behavioral scientists have devoted substantial effort to studying the impacts as well as the processes by which such policies come to be adopted. This section examines the former. (For the latter, see, e.g., Fritschler and Rudder, 2007; Kagan and Vogel, 1993.)

In 1999 the World Bank described and evaluated a wide array of tobacco control policies in countries around the globe (Jha and Chaloupka, 1999). The research documented in that volume and its more detailed companion book (Jha and Chaloupka, 2000) became the evidence base for the policy requirements of the WHO's 'Framework Convention on Tobacco Control' (FCTC) – the world's first global health treaty, now ratified by 177 nations (Framework Convention Alliance, 2013). A major goal of the FCTC is to get LMICs to adopt the basket of evidence-based tobacco control policies that have reduced smoking in developed nations. Those countries that have devised and invested in serious national plans to curb tobacco use have achieved considerable success, beginning with Norway in the 1970s and, more recently, Canada and Australia, each of which has driven smoking prevalence down, faster and lower than the rest of the developed world. Recently, a few countries in Central and South America have developed significant national tobacco control plans, including Uruguay whose aggressive graphic warning legislation has earned the ire of – and a lawsuit from – Philip Morris International. The US Department of Health and Human Services announced a national plan to combat smoking in 2010, the first such national effort in the United States (US Department of Health and Human Services, 2010). California, the state that has achieved most success in tobacco control in the United States, has had an orchestrated state tobacco control program for years (California Department of Health, 2013), although it has struggled through several attempts by the state legislature to redirect funds targeting tobacco control.

Three specific tobacco control policies have commanded the greatest amount of research attention: taxation, smoke-free workplace and public place legislation, and bans on advertising and promotion. We focus below on the social and behavioral research related to each.

Taxation

Research, primarily by economists, has established that taxing cigarettes is among the most effective measures to decrease smoking (Chaloupka and Warner, 2000; Chaloupka et al., 2012). Because the quantity of cigarettes consumed declines by an amount proportionately smaller than the associated tax rise, taxation increases government revenues at the same time that it decreases smoking. In developed countries, economists find that a 10% increase in cigarette price induces approximately a 4% decrease in quantity demanded. In developing countries, the demand impact may be twice as large. Effective dissemination of research findings has made taxation one of the central tenets of a comprehensive tobacco control program and a major component of the Framework Convention on Tobacco Control.

Although the 'bottom line' about taxation is well established, research by economists and others points to concerns that remain unanswered. For example, does taxation discourage the initiation of smoking? Although evidence preponderantly suggests that it does, a few studies challenge the conventional view (Chaloupka and Warner, 2000; Chaloupka, 1999). 'Side effects,' or subtle unanticipated impacts of taxation, warrant additional attention as well. Notably, one study found that increases in cigarette tax in the United States caused some smokers to switch to higher nicotine cigarettes to get their customary dose of nicotine from fewer cigarettes, particularly among younger smokers (Evans and Farrelly, 1998).

In the relatively new field of behavioral economics, a small cadre of psychologists is studying experimentally how smoking responds to incentives. For example, investigators give subjects a daily 'budget' (e.g., play money) with which to buy cigarettes, food, and other commodities, at prices established by the investigators, and evaluate the effects of 'taxation' by raising the price of cigarettes. Findings generally have been quite consistent with those in the mainstream economics literature (Chaloupka et al., 1999).

Behavioral economics can investigate questions not addressable using existing real world data, but the approach also has decided limitations in predicting how people will respond to price changes in the real world. By learning from each other, the two fields can enrich the evidentiary base for future tobacco tax policy.

Smoke-Free Workplace and Public Place Legislation

Smoke-free laws, originally labeled 'clean indoor air laws,' restrict or prohibit smoking in public places and workplaces. Legislation grew out of concerns that the exposure of nonsmokers to environmental tobacco smoke (ETS) could create risk of disease, leading in the United States to rapid diffusion of state laws beginning in 1973. A decade later, similar laws emerged at the local level of government, followed by much stronger state laws beginning in the early 2000s. Indeed, since the first truly comprehensive smoke-free workplace law was adopted in the state of Delaware in 2003, some 30 states have implemented completely smoke-free workplace legislation, laws that cover all restaurants and bars as well as other workplaces. Internationally, over 30 countries have adopted completely smoke-free workplace laws, led by Ireland in 2004.

The scientific knowledge base actually followed early diffusion of clean indoor air legislation, with a number of studies of the relationship between ETS exposure and the risk of lung cancer published in the 1980s (US Department of Health and Human Services, 2006). By the 1990s, the research base had become sufficiently strong for the US Environmental Protection Agency (EPA) to declare ETS a 'Class A Carcinogen' – a proved environmental cause of cancer in nonsmoking humans. The EPA also detailed nonfatal respiratory disease effects of ETS, particularly in children (US Environmental Protection Agency, 1992). Thereafter, research

implicated ETS in heart disease deaths in adult nonsmokers, possibly in an order of magnitude greater than the lung cancer impact (US Department of Health and Human Services, 2006).

Social and behavioral scientists have informed the debate by studying the process of the emergence and diffusion of clean indoor air laws and, subsequently, the effects of such laws on nonsmokers' exposure to ETS and on smokers' smoking behavior. Studies have found generally high levels of compliance with the laws even in bars, and reductions in employees' exposure to ETS, as measured by self-reports, air sampling, and examination of employees' body burdens of cotinine, a nicotine derivative. Other research has demonstrated that smoke-free laws increase the smoking cessation rate and decrease daily smoking by continuing smokers. Research by social scientists has established that hospitality industry venues – primarily restaurants – do not lose revenue following the adoption of smoke-free laws, a finding that has played an important role in debates about the desirability of laws covering restaurants and bars (Warner, 2006). Recently, the most dramatic finding to emerge from analysis of the effects of smoke-free laws is that jurisdictions that adopt such laws see a decrease in hospital admissions for acute myocardial infarctions (Lightwood and Glantz, 2009). Over 100 studies worldwide have documented the phenomenon. The idea that a law prohibiting smoking in public places and workplaces could reduce heart attack deaths by possibly 10–20%, (common findings in the studies), suggests that such legislation may be one of history's most effective public health interventions.

Advertising and Promotion

A diverse group of sociologists, psychologists, economists, marketing specialists, and public health scholars has studied the effects of marketing on smoking. Research by several scholars concludes that modern Western-style advertising creates an imagery that many people, including large numbers of children, find easily recognizable and attractive. There is a strong correlation between children's interest in cigarette marketing campaigns and their subsequent smoking behavior. Temporally, advertising campaigns directed at specific segments of a population have often been followed by significant growth in smoking in the targeted groups, including women in the US in the 1960s, young women in Asia in the 1990s, and children in many countries (Warner, 2006).

Whether any of these associations constitutes a causal relationship is the essential question. The same unidentified factor that makes cigarette advertising attractive to certain children could account for their subsequent smoking, independent of the advertising per se. Similarly, cigarette marketers might foresee an (independently occurring) expansion of a market segment and dive into the advertising void to compete for shares of that new market.

In the absence of the ability to run randomized controlled trials, the empirical analysis of the relationship between cigarette advertising and consumption has been unable to prove a causal connection between the two or to estimate its likely extent (US Department of Health and Human Services, 1989; Warner, 2006). However, strong evidence supporting causality comes from a study reexamining data on the relationship between countries' policies with regard to cigarette advertising (ranging from no restrictions to complete bans) and levels of smoking within those societies (Saffer and Chaloupka, 1999). Blending marketing theory with empirical analysis, this study concluded that a complete ban on cigarette advertising would decrease smoking by about 6%, while partial bans (e.g., banning cigarette ads on the broadcast media) would be unlikely to have an impact on cigarette consumption.

Combined with the previously existing evidence, this study leads to the most plausible interpretation of the relationship between advertising and cigarette consumption. It is a conclusion that probably will satisfy neither tobacco industry defenders of the 'brand-share only' argument, nor tobacco control advocates who condemn marketing efforts as the principal cause of smoking. Cigarette advertising and other forms of marketing probably do increase the amount of smoking in a statistically significant manner. (The amount is likely to vary among societies, depending on the maturity of the smoking market and on familiarity with large-scale marketing campaigns.) The converse, of course, is that advertising and marketing almost certainly do not account for the majority of cigarettes smoked. For this, one must turn to other influences, all less policy-tractable than advertising, including role modeling, peer behavior, and the addictiveness of nicotine and smoking.

Interaction of Policies

As policy research has become more sophisticated, the relationships among policies and their impacts have come to be better understood. Illustrative is research examining the joint effects of tax increases and the adoption of clean indoor air laws. For example, some of the smoking decline credited to tax increases might be associated with a citizenry more interested in reducing smoking. In turn, the latter could be reflected in the adoption of clean indoor air laws. Examining the joint effects of the two policies confirmed researchers' suspicions, thereby suggesting a reduced (but still quite substantial) impact of taxation on smoking. Similarly, disentangling the impacts of state-level tobacco control programs that mix tax increases with media antismoking campaigns is important but analytically challenging. Several research studies pave the way toward better evaluation of multiple-component policies (Warner, 2006). There is widespread agreement that effective tobacco control requires a multiple-component policy environment (Warner, 2000). Hence the need to better understand the interactions among policies.

The Future of Social and Behavioral Science Contributions to Tobacco Control

Social and behavioral science have contributed greatly toward understanding how and why the epidemic of smoking has evolved throughout the twentieth century. They have also elucidated a set of tools that can help society to extricate itself from the tenacious grip of this public health disaster.

With innovations in information and pharmacological technology combining with better insights into human behavior, we can anticipate further improvements in assisting smokers to quit. Although the long-range goal must focus on preventing future generations of children from starting to smoke, helping current adult smokers to quit remains critical to reducing the tobacco-attributable burden of disease and mortality over the next several decades; reductions in youth initiation will not show up in aggregate mortality numbers sooner than 30–40 years following the change in initiation rates.

The effectiveness of efforts to encourage smokers to quit depends to a significant degree on the environment in which smoking occurs. If smoking is increasingly viewed as antisocial, quitting smoking will become easier and more urgent for current smokers. Policy making is society's best means of intentionally altering the environment; and better understanding of the effects of policy interventions and how they come to be adopted will be crucial to shaping the environment with regard to smoking in the coming years.

The multidimensional problems associated with tobacco use vividly illustrate the need for scientists of all disciplinary persuasions to work together. The next great challenge confronting the diverse fields of social and behavioral science in tobacco control lies in learning how to combine the methods and insights of the various disciplines into an integrated whole.

Social Action and Social Justice

Sarah Todd, School of Social Work, Carleton University, Ottawa, ON, Canada

Abstract

Social work is unique as a profession, largely as a result of its commitment to addressing both individual problems and the social conditions that create and sustain those problems. Social action, social justice, and organizing for change are integral to social work, but their prominence has varied throughout the profession's history, largely in relation to the visibility and activity of broader social movements. In contemporary social work, social justice remains centrally important, but is operationalized more in daily practice and rarely linked to social movements.

Introduction

The International Federation of Social Workers and International Association of Schools of Social Work collaborated in 2000 and 2001 to create a shared definition of social work. Included in that definition are the statements that "the social work profession promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well being" and that "principles of human rights and social justice are fundamental to social work" (www.ifsw.org). Social work's intellectual core is unique because of its simultaneous concern with the problems faced by individuals, particularly those who are marginalized, vulnerable, and oppressed, and the larger structures and social relations that create and sustain individual struggles (Reamer, 1994). However, this dual commitment is not without tension. The social work definition of social justice is murky and the profession's actions often reflect this lack of clarity. At times, social work has aligned with dominant ideologies that marginalize and harm disenfranchised communities. For example, social workers continue to be heavily engaged in practices of surveilling poor people, particularly around parenting. This surveillance, while couched in supportive language, is invasive and regulatory. As Margolin (1997) notes, in many social work interventions,

> Members of the dominant group are active, and members of the subordinate, passive: one party sees, the other is seen; one writes, the other is written about; one purveys knowledge and direction, the other gratefully absorbs and obeys. And while not all families involved in these programs are on the same economic plane, there is a continuing story of economic deprivation: living below the poverty level appears again and again as clients' distinguishing characteristic.
> p. 176

At other times, and in other contexts, the fact that social work occupies a space so directly linked with those who are disadvantaged by global economic and social inequality has meant that workers within the profession have played the roles of initiator, facilitator, advocate, and ally, concerned with how inequality harms individuals and groups. An example of this is the work of Jayesh Patel, who cofounded the nongovernmental organization Manav Sadhna in Ahmedabad, India, in 1990. Manav Sadhna collaborates with people living in poverty to support children enrolling and attending school, facilitate women's economic independence, and ensure people in the community have enough to eat. Social work's conceptualization of social action and social justice has been most significant in terms of imagining a way for those who work closely with the state to ally with social movements for social justice.

Many social workers work in organizations that receive state funding and also support public community protests against how states sustain and exacerbate economic inequality. Throughout the world, social workers have allied with people in poverty, whether this is through participation in Occupy Movements, activism against austerity measures and the facilitation of community-based survival strategies in Greece, or involvement in United Nations-Habitat programs in Nairobi, Kenya, that seek to improve the overall well-being of people living in slums through addressing human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), shelter, inadequate services, unemployment, and land tenure.

There are, arguably, three types of social work interventions: those that are focused on maintaining the social order, those that are therapeutic in nature, and those that are focused on social transformation. The social transformative focus in social work is concerned with questions of how power is distributed among people, historical injustices against minority groups, the recognition of disenfranchised groups, and the distribution of resources (Dominelli, 2009). It raises concerns about the ways in which societies historically devalue and stereotype groups of people so as to justify and maintain unjust laws and distribution of resources. The resulting interventions are concerned with "ensuring social justice at individual, group and community levels and in seeking structural change to make this happen" (Dominelli, 2009: p. 13). In seeking structural change, transformative interventions tend to rely on organizing groups for collective action. For example, social workers with the First Nations Child and Family Caring Society have spent years challenging the structural inequalities facing indigenous communities in Canada, including poverty and inequities in access to education, health care, and adequate housing. The organization has initiated a number of collective action campaigns to mobilize citizens to work toward social justice for indigenous people in Canada.

Mapping Social Work's Commitment to Social Justice

Social work's commitment to organizing for change, as opposed to solely intervening in the lives of individuals, has two interrelated historical paths. Much of the profession's investment in collective action comes out of the successes of community-based activism by people of color and people living in poverty, such as the civil rights movements, indigenous people's movements across the globe, and global protests against the exploitation of people and resources in the Global South (Lee, 2011). These social movements have challenged therapeutic approaches to social problems, encouraged the profession to adopt a stronger focus on social justice, and informed the profession's understanding of how one can engage in social action to create change. Their influence has driven social work to challenge oppression through a wide range of issues, including racism, sexism, ableism, colonization, heterosexism, and poverty (Thompson, 2002). In particular, people living in poor communities have repeatedly raised their voices to critique the often dehumanizing and humiliating mechanisms through which various governments respond, or fail to respond, to their needs. In turn, they have challenged social work to critique and challenge the profession's complicity in these systems.

A second historical path started with the late-nineteenth-century settlement house movements, which were first founded in Britain and then exported to North America. The most famous settlement house worker was Jane Addams, a Chicago-based social worker whose innovations in working with disenfranchised communities provided much of the intellectual and practical foundation for the social work profession. Jane Addams preferred collective approaches to resolving social problems, seeing society's harms in sociological rather than psychological terms. This was, and continues to be, a disruption of much of social work practice that has aligned more closely with psychological theories. Settlements involved mostly middle-class people living in impoverished communities and provided a range of community-based interventions to help community members address their own problems. Settlement workers' strategies for change included those that the communities could create themselves, research into the social conditions in which people were living, and social action to achieve state-level legislative changes. Settlement movements engaged local citizens to create support groups and recreational programs, establish health clinics, build playgrounds, create juvenile courts, and organize protests to change labor laws and other key pieces of legislation that were seen as oppressive (Stebner, 1997).

The influence of settlement house movements can be seen in the work done by social workers in the contemporary context. For instance, in Ontario, Canada, community health centers are situated in impoverished communities and have a mandate to serve them. The social workers in these centers support citizen campaigns to affect policy and legislative change and work with community members to organize community kitchens and gardens, homework clubs, recreational programs, and all-candidate debates. Thus, social workers collaborate with citizens to establish groups and programs within the community as a space of 'prefigurative politics,' where disenfranchised persons use the skills they develop in the local sphere to engage with broader social movements (Breines, 1989). When social workers organize for social change, it is often about engaging people who have had little opportunity to influence their own environments, so that they can have a collective experience of affecting change. While social work interventions are usually much smaller scale than those witnessed in social movements, they are the space in which many citizens gain their first experiences in joint action and build their ability to work toward social justice. For example, in many disenfranchised neighborhoods, organizing an all-candidates meeting during elections exposes people to the political platforms of politicians and creates the opportunity for community members to understand what those platforms mean for their daily life. This is often one of the first times when many members of disadvantaged communities engage with the political process and begin to see that by having a political voice they can sometimes impact their community's health and well-being.

While the community-based social work that began in the nineteenth century has had a recent resurgence in certain parts of the world, overall, the social work practice of organizing for change has waxed and waned in popularity. After the settlement house movement and the depression years, there was a strong focus on professionalizing social work combined with the marginalization of social activism. The profession's commitment to social action and social justice then resurged with the social movements of the 1960s and 1970s. For example, social workers were quite active during the women's rights movement of the 1960s and this, in turn, challenged social work as a profession to attend to the ways social policies and social work practices impacted on women's lives. Since the 1980s, writers have observed an enduring discourse of social justice, but one that has been largely focused on day-to-day justice rather than the social, economic, and political systems that sustain inequality (O'Brien, 2010). Social justice work today seems to involve a range of activities including engaging in advocacy, negotiating unjust systems, and treating marginalized people with dignity and respect (McLaughlin, 2011). At times, social work is a profession that pushes social justice agendas, but often social movements are challenging the profession to recommit to social justice. For example, social workers in a particular geographic area may work with people who come together for joint action because of an oppressive issue affecting those who share a physical space or because they have a common experience of identity marginalization. Social workers have often worked closely with communities affected by environmental degradation due to oil sands developments or nuclear energy plants, or in communities that have been adversely affected by the destruction of fish stocks due to international overfishing practices (Lundy, 2011). Social workers such as John Coates (2003) have challenged the profession to center ecology in our understandings and work for justice. More recently, Lena Domnelli (2012) has argued for green social work that integrates concern for human needs with an understanding of physical environments and the biosphere.

In the current neoliberal context of global politics and economics, social workers have found it challenging to be involved in social action. There have been times when the principled statements of the profession's commitment to social justice have seemed marginal in social work courses and have

been rarely integrated into practice (Specht and Courtney, 1994). However, there remains quite a bit of variation around the world in terms of how much schools of social work and social work practitioners have been able to maintain a social justice focus in their pedagogy and work. While much social work practice in the United States and Britain has shifted away from a commitment to creating social change, the profession in Latin America and the Caribbean has created and sustained progressive elements. In other nations, such as the United Kingdom, Canada, and Australia, there is a strong intellectual tradition in critical and structural social work, but the struggle remains to maintain that focus in practice (Ferguson, 2008).

The history of social work also includes a never-ending tension between the notion of professionalization and social activism. There has always been a debate as to whether social work should be part of a movement to achieve social justice or whether it should primarily be a profession with evidence-based practices deployed to help individuals, groups, and communities adjust to their environments (Olson, 2007). This tension is observable when comparing the work of authors such as Martin Davies, who, in his book, *The Essential Social Worker* (1981/1994), understands social work as a centrist profession that is focused on the compassionate care of vulnerable individuals. In contrast, writers such as Maurice Moreau (1979), Dominelli and McLeod (1982), and Fook (1993) conceptualize social work as a profession that attends to how relations of heterosexism, abelism, racism, sexism, and capitalism shape people's individual problems and is thus highly political and collectivist in nature. Professional credibility is important in market economies and essential for gaining political, economic, and social control over an occupation, and the progressive and social activist elements of social work are seen by many as a threat to this credibility (Figueira-McDonough, 2007). Empirical research from the United States has suggested that as social work professionalizes, members become more involved with conventional politics and less involved with broad social movements; however, given growing social movements concerned with global inequality and injustice, social workers may once again repoliticize and organize around structural issues (Reeser and Epstein, 1990; Hoefer, 2012). The challenge for many in the social work profession continues to be how to craft a notion of professionalism that is consistent with a commitment to equality and social justice.

Conceptualizing Social Action and Social Justice

Much work has been done in recent decades to clarify the nebulous terrain of social justice within social work. The profession's conceptualization of social justice is informed by theorists such as John Locke (1988), John Rawls (1999), Carol Gilligan (1982), Grace Clment (1996), Friedrich Nietzsche (2008), and Amartya Sen (2011). The breadth of these authors and their ideas about social justice is reflected in the profession itself having a diverse range of conceptions of social justice. One of the most useful definitions of the concept was developed by Craig (2002), who states that social justice is

> a framework of political objectives, pursued through social, economic, environmental and political policies, based on an acceptance of difference and diversity and informed by values concerned with: achieving fairness, and equality of outcomes and treatment; recognizing the dignity and equal worth and encouraging the self esteem of all; the meeting of basic needs; maximizing the reduction of inequalities in wealth, income and life chances; and the participation of all including the most disadvantaged.
> pp. 671–672

This vision of social justice reflects the profession's dual mandate to attend to the individual and the environment that shapes people's lives. As a result, the profession's understanding of social justice is one in which broad-scale structural justice goes always hand in hand with the quest for individual well-being. We attend to social justice in micro and macro relations of power. This dual focus has created some ambiguity, but it is also the space of innovation that social work brings to the concept of social justice. In addition, the social work profession has worked to refine definitions of social justice so that they can be operationalized.

Social justice is understood to be a realistic choice for individuals and societies. Social justice, in this construction, is not abstract, but is instead achievable through the small and large decisions individuals, institutions, and societies make. The injustices of society are constituted and maintained by people, and so can be challenged and disrupted. Gil's (2008) conceptualization of social justice includes three dimensions: individual human relations, values and social institutions, and global human relations. This last aspect of social justice has been vitally important in recent decades, as the profession has had to grapple with the fact that injustice within a local community can have long links to distant corporations, policies, and nations (Lundy, 2011). While globalization has resulted in the intensification of wealth in a handful of corporate conglomerates in cities such as Toronto, London, New York, and Tokyo, it has also meant austerity, job losses, and a downward shift in wages in many smaller communities around the world (Workman, 2003). As a result, the profession has had to develop new strategies for achieving social justice, with each dimension requiring its own style of intervention. At times social workers are using restorative justice circles within communities to address micro aspects of social justice (Baskin, 2011). At other times, professionals are working with institutions to develop policies and processes that address injustice or aligning with social movements to address global inequality. In this way, social justice is conceptualized as a multidimensional concept that includes concern for the distribution of resources (distributive justice), the individual or community's right to self-determination, the promotion of welfare or well-being, and substantive equality (McLaughlin, 2011). By combining all these elements into a single understanding of social justice, social work draws upon both class-based conceptualizations of inequality and those that have emerged in more recent decades through identity-based social movements (Lundy, 2004; Mullally, 2006). This conceptualization of social justice is one that is flexible, relevant to work with individuals and communities, and achievable. Overall, it remains important to define social justice in a way that all social workers, whether working in therapeutic settings with individuals, as gatekeepers

of state resources, or engaged in social action can see resonating with their practice.

Operationalizing Social Justice: Organizing for Change

When social workers engage in social action to create social change, they do so mainly by organizing community groups. The change that social workers attempt to achieve by using community organizing methods is multifaceted and includes facilitating and organizing communities to meet their own needs more effectively and to make demands on the state or private sector to redistribute resources. Social work organizing practices are shaped by ideas from organizers such as Paulo Freire and Saul Alinsky, whose writings have helped conceptualize the principles of and approaches to organizing for social change, and by contemporary social movements including the feminist, disability, and queer movements.

Paulo Freire's work on popular education has influenced the role that social workers take when organizing for change. In his seminal publication, *Pedagogy of the Oppressed*, Freire (1972) conceptualized the role of a popular educator as one who works with communities to help them develop a critical consciousness of what is happening in their world and how this shapes their daily existence. The practice of popular education is useful for social work because it outlines a process of education that analyses ideological and structural power relations. A popular educator is one who works to establish a relationship with communities based on values of critical compassion and a strong commitment to social transformation. It is a role many social workers take on when working with members of marginalized communities. Popular educators are seen as colearners in the communities with whom they work. This notion is congruent with the practices of the settlement house movement where members of communities were encouraged to learn from one another. The settlement house movement began with the London-based Toynbee Hall, which was founded on the radical idea that academics, activists, and people living in poverty could live and work together to create practical and political strategies to address poverty. Those working in the settlement house movement not only pushed the state to respond to human needs, but also offered services and programming to fill in where the state could not or did not (Bradley, 2009). Freire's notion of praxis provides an opportunity for social workers to develop their reflective skills when working with communities. All effective action must be preceded and followed by a period of reflection that then informs future actions. This phase of reflection includes a focus not only on the pragmatics of any approach used, but also on individual and group emotions. Freire (1990) saw social workers' use of personal stories to inform political action and the profession's ongoing reflection on relations of power, privilege, and empowerment as integral to social transformation. Freirian writing has enriched the field of community organizing within social work so that the core of social action is grounded in the personal stories of disenfranchised people. Individual stories become the collective narratives that express the hopes and fears, needs and strengths that are the basis of social work for change.

Freire's writing also influences social work's awareness of the ways in which poverty and powerlessness erode hope, resulting in silence and disengagement. Within social work, social action is used as a means of reengaging people to create change in their lived environment. This, in turn, rebuilds hope. Freirian approaches to social action have created space to link spiritual dimensions of human experience with revolutionary change (Hope and Timmel, 1984). While social work's notion of social change is purely a secular one, many social workers are motivated toward the profession because of spiritual commitments and many communities rely on their spiritual practices as a source of hopefulness and strength to sustain them during difficult times and through the change process. Freire articulates a way to imagine processes for social change that do not rely on the influence of institutional religion, but can draw upon radical spirituality as a means to foster hopefulness.

In addition to Paulo Freire's writing, social work's approach to organizing for change has been influenced by the writing of Saul Alinsky, who articulated a clear process for social action involving confrontation with power holders. While Alinsky worked in the 1940s to 1960s, many activists still use his strategies to change neighborhoods in the United States, United Kingdom, Australia, and Korea. His approach to social action offers an alternative for social workers who are predominantly schooled in practices of consensus building. While skills for achieving consensus are helpful when organizing, social workers who are engaging in social action often find themselves in a more confrontational relationship with the state and companies that fail to fulfill their obligations to marginalized citizens. Alinsky perceived organizing as a battle between the haves and the have nots and felt that one fought this battle by any means necessary and with little concern for ethics and morals. His writing offers concrete tactics for social workers to use when having to confront opposition. Alisnky's approach to organizing is quite male-centered, focused on formal justice. Since his death, feminists and others have built upon his model, integrating his approach with a more women-centered focus on relationships and the politics and practices of caring (see Stall and Stoeker, 1998).

Like Freire, Alinsky firmly believed that social action had to be grounded in the experience of the people with whom one is working. His approach involved uniting citizens around their own self-interest and protesting in ways that were outside of the usual means through which people express dissent. In particular, he used large-scale, creative techniques that stayed close to his member's experiences, but grabbed media attention and threw his opposition off balance (Alinsky, 1971). Alinsky understood social action in pragmatic terms. He felt that social action needed to target the causes of people's oppression, not the symptoms, and he outlined a process of agitating for change, antagonizing power holders, educating the public, and organizing people. He believed that in order for communities to be able to sustain themselves through the social change process, they needed to be highly structured, with clear roles and responsibilities. One of Alinsky's most underrated yet significant contributions to social work's notion of organizing for change is that he saw the role of the community organizer as a professional activity. By reworking community organizing in this way, he offers an opportunity to imagine professionalism as including a commitment to highly politicized social action.

Social movements have also shaped social work's approach to organizing for change. From feminist movements, social workers have learned to work in a process-oriented way to achieve their goals and to use consensus-based processes. In addition, the feminist movement's view of power as limitless and the strategies used to link people's private experiences to public action have been instrumental in social work's approach to social change in impoverished communities. Finally, social work has drawn extensively on the writing and practice of feminist organizers who have struggled with embracing diversity within the movement (see, Naples, 1997). This component of the movement has challenged social work to create inclusive ways of organizing diverse groups. Practices such as creating caucuses have been integrated into mainstream approaches to organizing in social work.

The consumer mental health movements, antiracist, and disability movements have also challenged the way the profession organizes. And finally, the lesbian, gay, bisexual, transgendered, and queer movements and queer literature have had their own impacts, challenging the profession to consider how our labeling of communities, even with terms then used to mobilize public support and create services, does little to create revolutionary change. These movements have challenged the profession to move away from identity labels, to work with groups and awareness about how social discourses shape the stories communities and individuals tell one another, and to reflect upon how often the social work vision of marginalized communities is one that furthers the profession's agenda rather than their experience (Willis, 2007; Siddiqui, 2011). For example, queer theorists have argued that social work's conception of lesbian, gay, bisexual, transgendered, two-spirited, and intersex youth as struggling and suicidal is used to justify the profession's interventions in their lives, whereas the movement of school-based gay-straight alliance clubs is a community-based initiative built on the vibrant strengths of the community, which does not require professional interventions (Willis, 2007). These are ongoing reminders to the profession that social workers' first job should be to support communities in achieving their own vision.

The influence of key social movements and social activists has helped to refine the way social workers conceptualize social action and organize for change. In particular, social workers organizing for change see their work as professional practice by reimagining professionalism as a role of colearning where professionals bring particular understandings of power and the change process to engage in a process in which the stories of people who are oppressed inform their working relationship and social justice goals that are imagined (Ledwith, 2011). This professionalism is also deeply rooted in the ethical responsibility to align with the most marginalized in society and seek social justice for these groups. Through a process that is grounded in individual storytelling and a critique of the root causes of oppression, social workers organizing for social change continue to focus on the profession's dual mandate of attending to the individual and the structures of oppression that shape their lives.

Contemporary Challenges and Conclusion

While the work of organizing for change remains vital to progressive social work's vision for social justice, contemporary challenges and cautions need to be addressed. Western neoliberal governments have dramatically shifted the responsibility of services and programs from the state to the community, which reflects a significant shift away from the welfare state and the idea that the state has a direct responsibility for the well-being of its most marginal citizens (Kelly and Caputo, 2011).

This shift to community has had a number of worrying effects. First, communities have become known entities in which members are increasingly mapped, classified, and surveilled for the good of a wider community. Anyone can now find out a community's median level of income, the ratings of local schools, the racial and linguistic diversity within a geographic area, the average rate of rental accommodations, and crime statistics. These statistics help to define and reify a community, which, in combination with a 24-h news cycle and instant media reports, means that disadvantaged communities can quickly become stereotyped and stigmatized. In addition, individuals and groups of citizens have had to become more responsible for their own well-being while the state is less responsible. While such a shift aligns well with contemporary language of independence and self-sufficiency, what is obscured here is that all communities require state support to function well and that there are advantages for all when the state takes collective responsibility for services such as clean water provision. The final concern, and possibly the most pressing for social work, is that downloading this responsibility to communities has resulted in community-based agency staff becoming spokespeople for those communities, obscuring the organizations' own interests and agendas and prioritizing those over the community's needs. Community interventions are highly desirable in neoliberal contexts; they are efficient, cost-effective, and yet deny the reality that many local neighborhoods no longer have the capacity and resources to effectively address the problems that they are facing, which are often the result of extralocal forces. As a result, the state increasingly controls the local without taking responsibility for it (Kelly and Caputo, 2011). Social workers can play a key role in this process by working with communities to assess the positive and negative consequences of various community funding opportunities and programs.

The notion of community that is mobilized to affect the neoliberal agenda is a nostalgic one, where communities are imagined as wholly good spaces defined by informal care, dignity, and respect (Joseph, 2002). This is set in opposition to the supposedly dehumanizing and depersonalized state-delivered services that are managed through bureaucracies and institutions. By reifying community in this way, the state is able to pull out of more and more obligations to its citizens. Its place is being taken by an increasing privatization of services that are often marketed in the long lost language of community (see Dominelli, 2004). For instance, privatized services for seniors are marketed using the terminology of homefulness and as retirement or care communities. These nostalgic renderings fail to account for the reality that the local community has always been a space of exclusion and rigorous social control just as much as it has been a space of support and inclusivity (see Dominelli, 2006). Communities tend to take care of those who fit within their norms, and they also struggle with and exclude those who transgress the norms or

expectations of the group. The secondary problem with this nostalgic rendering is that it comes from communities with flourishing agricultural or manufacturing bases from which people were able to meet their basic needs. This is not the reality of many marginalized communities today (Kelly and Caputo, 2011). Contemporary global exploitation has resulted in massive shifts in production and left many communities unable to access the jobs necessary to sustain themselves. Thus, while organizing for change often relies on intervening at the level of community and this holds a great deal of potential for achieving some measure of social justice, it also has its dangers and cautions as this approach to social change can in fact work to sustain broad relations of inequality by distracting people from the root causes of their economic marginalization.

These tensions create a significant amount of pressure on social workers who are organizing communities. That they must perform a careful dance, balancing the basic needs of the community and engaging in the social action necessary to link their local work to broader social justice movements, and social change because a collective intervention is not, in and of itself, necessarily progressive. For social workers' interventions in the community to be oriented toward social justice requires community workers to develop deep alliances with social movements that have a greater distance and independence from the state. The flexibility and critiques of social movements help to challenge the profession continually to reflect and rework its approach to social change to ensure that social workers are achieving social justice. For example, those involved in disability movements, movements of people living with HIV/AIDS, and mental health service users/survivors movements have challenged the profession critically to reflect on how we perceive, involve, and respond to people living with disabilities, people living with HIV/AIDS, and people who use mental health services (Beresford, 2000). Feminists also did this in the 1960s and following their critique they set up services run for and by women (see Dominelli and McLeod, 1982).

There is significant concern that the place of social justice in contemporary social work has been marginalized through new managerial processes and politics. While this has produced a significant strain on the profession that has limited the profession's capacity for social action, social justice seems to remain a priority. The opportunities for social workers to effect change at the broader political and structural levels have been reduced substantially, but practitioners are still operationalizing these issues in their daily practice (O'Brien, 2010). The contemporary struggle of many in the profession is in how to link these daily practices to social action. For those organizing communities for change, the struggle is how to sustain these interventions in the direction of social justice and not to facilitate the state's ongoing negation of its responsibility to care to disenfranchised members of our societies.

Throughout the vast literature on social justice and social work, there is a clearly articulated vision for the future of social work, one that is deeply aligned with the anticapitalist and global justice movements of our time and, through such alliances sustains a radical edge pushing for social change (see Ferguson, 2008). It seems likely that such a radical frame might help to protect against some of the dangerous co-optations of community-based practice that social work has seen happening under neoliberal regimes and to sustain the professional commitment to social action, social change, and social justice.

Social and Behavioral Sciences under Dictatorship

Abstract

Various forms of dictatorship have been a context in which social and behavioral sciences (SBS) have been developing through most of the twentieth century. Nazi and fascist regimes in Europe, Communist single-party states, military juntas in Latin America and elsewhere in the postcolonial world accompanied the crisis of tradition and development of modernity as an alternative to liberal democracy. Dictatorships have thoroughly affected the history of SBS pursuing a policy of repression and control and, sometimes, encouraging a growth of various social science disciplines. The lack of intellectual and institutional *autonomy* is generally endured, though to different degrees and in different aspects, by SBS under dictatorship.

Dictatorship, Social Sciences, and Modernity

The relatively short history of social sciences has been heavily impregnated by uneasy yet pervasive relations with various forms of dictatorship. Dictatorial (i.e., nondemocratic) forms of government have dominated in different regions of the world through most of the twentieth century. According to the Human Security Report (2011), in 1946 only 20 countries (28% of the world's governments) can be counted as democratic, while by the end of the century their number goes up to 79, and continues to grow ever since (by 2008 that share has more than doubled). Dictatorships accompanied the crisis of tradition and development of modernity as an alternative to liberal democracy. The latter, established as a normative model of the modern government, has failed to stabilize itself, with a few notable exceptions, in the biggest part of the world before the end of the twentieth century (O'Donnell, 1972; Brooker, 1995; Kim et al., 2013). Consequently, it should be stressed that nondemocratic forms of government are not an exception, a deviation, or a hazard, as they are often perceived, but a structural part of modernity providing a most common context for the development of social sciences in both negative and positive senses.

In the years following the World War I, and especially during the Great Depression, the first wave of modern dictatorships – of Fascist or para-Fascist nature sharing antiliberal, anticommunist, and nationalist values – touched, for a more or less long period of time, many of the European countries. Nazi Germany's Third Reich and the loyal governments fell after the defeat in World War II, while Communist regimes were spreading in different parts of the world. For the first time, 'dictatorship of proletariat' emanated from the Russian Revolution and was transformed into the Stalinist regime of personal power in the late 1920s. Following World War II, this type of political regime was consolidated in a large part of the Central and Eastern Europe forming the Soviet bloc for nearly half a century. Communist dictatorships also proliferated, in the after-war period, in Southeast Asia (following the example of China), Africa, and some other parts of the Third World. Finally, numerous military dictatorships, stable or volatile, were established through the *coups d'Etat* in Latin America, and elsewhere in the new postcolonial societies.

Modern dictatorships have taken very different forms and have had various ideological inspirations (if any), so that a unique definition or a set of common features might hardly be formulated (Ezrow and Frantz, 2011). Some of them might have possessed at least some of the formal institutions of representative democracy (parliament, elections, etc.), been more or less repressive, to some extent respected the rule of law, and gained a popular support. However, a dictatorship can negatively be defined as a form of government that excludes political pluralism, competition, and prevents citizens from participation in decision-making. Power is often concentrated in the hands of an individual, a group of individuals (i.e., a *junta*), or a single party (merged with the State apparatus). Along with other recurrent features (cult of personality, abuse of individual freedoms, corruption, etc.), a political monopoly constitutes an essential difference between modern dictatorships and liberal democracies. To the extent to which a dictatorship tends to suppress any opposition, any critic, any public deliberation, it gives ground to a largely accepted opinion according to which social sciences can only exist in a democratic society.

Indeed, specific features of dictatorships are far from being neutral for the development of social sciences. The establishment of any dictatorial regime, accompanied by the elimination of political opposition, severely affects the situation of social sciences. Being particularly sensitive to political issues, social sciences undergo a profound restructuration (or even suppression) during the first years of dictatorship. Ideological campaigns and purges, repressions (expulsions and, in extreme cases, massive imprisonments and executions) are a widespread phenomenon. These campaigns might provoke massive exoduses of social thinkers and even entire schools. Karl Mannheim, Paul Lazarsfeld, Ludwig von Mises or Wilhelm Röpke, and the Ordoliberal school, exemplify the emigration of scholars (often of Jewish origin) from Germany and Austria to the United States and other countries. Similar movements, from Eastern Europe, included sociologists, economists, philosophers, and other social scientists opposed to the formation of proletarian dictatorships. These exoduses often engaged major figures as Mircea Eliade (from Romania), Tzvetan Todorov (from Bulgaria), or Pitirim Sorokin (from the Soviet Union), and considerably weakened national schools of social

sciences. Famous 'philosophers' ships' transported thinkers and scientists expelled from the Soviet Union in 1922. Those who stayed were often subjects to 'inner emigration,' dismissal from academic positions, or different forms of compliance with the officials.

The periods of intense repression and unification are normally followed by periods of a relative liberalization concomitant with stabilization of new institutional structures and routines. This 'normalization' can imply certain pluralism and autonomous thinking in the field of social and behavioral sciences (SBS). Nonetheless, unlike in democratic regimes, they can only achieve a reduced autonomy from political power. Public research and education institutions are systematically put under surveillance, and intellectual production is strictly controlled. Furthermore, social scientists cannot overtly discuss their ideas, and their production is mostly isolated from the public space and mass media. In other words, under dictatorship, social sciences can only be legitimately mobilized as specialized knowledge aimed at informing (and legitimating) decision-making, and not as an instance of independent thought able to criticize and denounce power. In the case of nationalist dictatorships, the symbolic function of SBS consists essentially to praise and to defend a national culture against international influences or critics.

The ambition of dictatorships to unify and control public discourses, which prevents social sciences from emancipation, might vary in degree according to the ideological nature and severity of a regime. The most important, and relevant for this discussion, distinction is the one that opposes totalitarian and authoritarian regimes (Linz, 1975). The former often follows a single-party state model, based on an extended social mobilization and a coherent official ideology. It tends to control every aspect of life of its citizens, and to exclude all differing opinions and lifestyles. Hitlerism and Stalinism represent two major figures of historical totalitarianism (Arendt, 1951). The authoritarianism, in turn, is less radical and comprehensive, and can be applied to any political system, ideologically ambiguous, but averse to competitive elections and republican procedures (Linz and Stepan, 1996). In spite of their great variety, due to their relative tolerance to public debate and political opposition as well as the absence of systematic intrusion in individual privacy, most Latin American dictatorships, and arguably some post-Stalinist regimes in Central and Eastern Europe, might be classified as authoritarian (O'Donnell et al., [1986]1991).

As ideal types, these two categories are landmarks in a continuum from the most top-down, monopolistic, and rigid system into different degrees of liberalization and tolerance. They can be also applied to describe different stages of the same regime. At the beginning dictatorships tend to be more rigid and coherent than in later stages. The distinction between totalitarianism and authoritarianism is crucial in a sense that while the former denies any independent intellectual production outside the State and the official ideology, the latter accepts a larger autonomy for social organizations and certain tolerance to opposition. As Stoppino (1983, p. 132) emphasizes, in authoritarian regimes, civil society corporations (as trade unions, pressure groups, lobbyists, or religious associations) persist and the independence of educational system and media is respected to a certain degree. Even political opposition can be tolerated if it is not in open competition with central powers.

Nonetheless, one should emphasize, once more, the variability of historical figures of dictatorships in their relations to social sciences. Differences in the situation of social sciences are related to historical contexts presenting various linguistic, politicoeconomic, and religious constellations. For instance, the Portugal (Salazar) or Spanish (Franco) dictatorships of conservative nature implied an alliance with Catholic Church and a mistrust of social sciences associated with modernist values (Giner, 1990). In turn, Nazi and Stalinist regimes were radically antiliberal and anticonservative in their ambition to promote a truly scientific government of society in line with the party ideology. Contrary to Communist states, later Latin American military regimes were market-friendly and welcomed international cooperation with (capitalist) countries, including external financial support for SBS development. The resulting patterns of institutionalization of social sciences under dictatorships are quite different. In some cases, authoritarian regimes give an impulse to institutional growth and internationalization of social sciences and, in many others, hinder these developments. The existence of developed national traditions of social sciences *before* the establishment of a dictatorial regime is also an important variable.

In what follows, two relevant, yet in many respects opposing, cases are considered: European Communist single-party states and Latin American military dictatorships. These cases are exemplary in a sense that, first, they possess established traditions of different fields of SBS (which have existed before, during, and after dictatorial periods), and, second, dictatorships were not just short episodes of the history of these regions, but were in place for many years or even decades, so that they have left a deep mark on the trajectories of social sciences. Each of these regional cases is characterized by a geographical and temporal unity, as well as politicoeconomical proximity. Common patterns, as well as variations within these cases, will be considered.

European Communist Single-Party States

Scholarship on the SBS under dictatorship in the USSR and Socialist bloc, but also in Germany and other European countries (Italy, Portugal, Spain, and others), is quite scarce. Dictatorship episodes are mostly omitted as obscure and unproductive for social sciences. External observers often depict Socialist sociology as being simply Marxist–Leninist orthodoxy (Keen and Mucha, 1994, p. 1). Scholars with experience of Socialist academia, on the other hand, sometimes lack a critical distance. Balanced accounts considering the sociological contexts of social science histories are rare. Although monographic studies of national disciplinary histories are accessible, attempts at comparative analysis are still in shortage (see, e.g., Koleva, 2002; Voříšek, 2008).

In the history of Socialist SBS, two phases can clearly be distinguished: strong dictatorship (Stalinism), established in the Soviet Union by the end of the 1920s and later imposed to new Socialist states after World War II, and the post-Stalinist period beginning with the Khrushchev 'Thaw' in 1956.

Stalinist Model

In the Soviet Union, non-Marxist approaches in SBS are to be banned from the early 1920s, but a relative pluralism of opinions within this paradigm is tolerated until the end of the decade. The 'Cultural Revolution' imposed by Stalin radically redefines the intellectual and institutional landscape of social sciences. This totalitarian move implies a complete cognitive and institutional unification under the lead of historical materialism. The conformity to Marxist–Leninist doctrine and class principle becomes the main criteria of scientific truth and objectivity. Sociology, psychoanalysis, but also genetics, and some other disciplines, are labeled 'false bourgeois sciences.' As a consequence, their development is brutally stopped in the Soviet Union in the 1930s for a few decades. Economic sciences, which have flourished during the 1920s, are not completely eclipsed, yet they undergo a rupture: the most visible schools and domains of economic research are suppressed. Numerous scholars engaged in these fields (including the prominent economists Nikolai Kondratiev and Alexander Chayanov) are arrested and later executed, many others are sent to Gulag or suspended from teaching and doing research. A new science, political economy of socialism, is painfully and slowly elaborated under the close scrutiny by Stalin himself. Nonetheless, some other branches of SBS scholarship (i.e., the Marxist history of science, in particular the work of Boris Hessen; the activity theory of Alexei N. Leontiev and cultural–historical theory of Lev Vygotsky in psychology) were developing during this period and even attracted the attention of Western colleagues.

This totalitarian model of social science resembles relations between political regime and academia in European Fascist and semi-Fascist states. During the period of dictatorship, the undergraduate teaching of sociology is forbidden in Portugal (Torres, 2010), and its development is virtually eclipsed in Spain from 1939 to 1950s (Giner, 1990). In Germany, sociology is not forbidden, but it has to conform itself to *Völkisch* ideology of the Third Reich: Nazi sociology is promoted against any other conception of social science (Western liberal or Marxist). Seemingly to the Stalinist class (Party) principle, it is the racial or ideological criteria that serve to distinguish between true and false: e.g., Durkheimian sociology is stigmatized as a 'Jewish,' and thus erroneous, social theory, while Max Weber is criticized for his 'liberal' orientations (Klingemann, 1996, p. 55). Methodological nationalism and intellectual autarchy are cultivated in social sciences aimed to contribute to the ideological legitimation and building of a new society. Western social theory is under suspicion in the Soviet Union and it is studied under the label of 'critique of bourgeois theories.' Most of the Western scholarship is classified, and can only be accessed, in the libraries, through a special authorization.

From 1948, the Stalinist model of social science is imposed to most newly established Socialist societies in the Central and Eastern Europe (except for Yugoslavia where Tito refuses to be subordinated to the Soviet Communist party but nevertheless monopolized academia). Social sciences are rebuilt to conform the theoretical framework of historical materialism (part of the Marxism–Leninism). In some cases, especially in Romania, purges take place against 'fascist' social scientists. 'Bourgeois sciences,' especially, sociology ceases to exist institutionally in almost all Eastern Europe at least until the end of the Stalinist period. 'Soviet institutes' are open to propagate the Marxist–Leninist social science. With this goal, Soviet scholarship (textbooks and collections of texts in the field of historical materialism and scientific communism) is translated into most East European languages (Keen and Mucha, 1994, p. 7). 'Fundamentals of Marxism' (Yugoslavia) or 'scientific communism' (USSR) aimed at strengthening ideological integrity, become compulsory subjects in all undergraduate curricula in the Socialist bloc.

In the Soviet Union, as well as in satellite countries, research in social sciences is mainly carried out within the Academy of Sciences, a centrally managed and publicly funded network of research and auxiliary institutions (Graham, 1967). Besides, a network of Party research institutions and schools destined to form political cadres is established with, at the head of the hierarchy, the institute of Marxism–Leninism depending on the Central Committee of the Communist Party. In this highly centralized and hierarchical system, independent or private institutions do not exist, and the publicly funded research and higher learning institutions are directly subordinated to the central Party organs and administrative bodies. The political influence is exercised through laws and regulations, and research planning. Throughout the Socialist period, very close ties, a sort of symbiosis, between party–state bureaucracy and academia are maintained, with the leading role of the Party (Krementsov, 1997, p. 4).

Post-Stalinist Social Sciences

In the years following the beginning of the Khrushchev 'Thaw,' i.e., from the end of the 1950s, social sciences undergo a process of an extensive institutional (re)building in the Soviet Union and satellite countries. Disciplinary infrastructures comprising research institutions, university departments, professional associations and reviews are created on the initiative or with approval of the central Party organs. In particular, sociology (re)appears as an academic discipline, though with a different pace and scale, in all Socialist bloc: first in Poland, Yugoslavia, and Czechoslovakia; and later, during the 1960s and the 1970s, in the Soviet Union, Bulgaria, the German Democratic Republic (GDR), Romania, and Hungary (Keen and Mucha, 1994; Voříšek, 2008). But it is significant that full sociological curricula and university grades in sociology appear quite late, if not only after the fall of dictatorships. As in the West, new social sciences are institutionalized: economic cybernetics (as a Socialist counterpart of mathematical economics), scientific forecasting of economic and technological development (while the Western-style futurism is banned), science studies, area studies (American, African, etc.), and so on.

The rationale behind these efforts is primarily the competition on the ideological front of the Cold War: to increase the presence of Socialist scientists and to disseminate the achievements of Socialist regimes on the international scene. International congresses abroad and inside the Soviet bloc serve this goal. Ideologically viable participants are carefully selected to represent Socialist countries in these meetings. Development of the Third World (from India to Africa) is a particularly important stake in the competition between the two super powers. Experts' activities funded by the State or private

foundations (in the American case), as well as student scholarships and exchanges, are promoted on both sides of the Iron Curtain. Second, social sciences come to be viewed as an important factor of the socioeconomic development: Socialist governments formulate a need for scientific expertise in social and economic matters. Hence, functions of social sciences, economy, and sociology in the first place, are conceived as to study complex social phenomena in order to deliver a 'scientific basis' to the construction of socialism. Various techniques of optimal planning, systems analysis and mathematical modeling of social and economic processes are promoted in order to satisfy this demand. According to this orientation, social sciences are mostly limited to empirical and applied research, which might have immediate utility. Nonetheless, facts of 'reality' established through the empirical research often contradict the official orthodoxy and present a source for dissidence (Levada, 1969; Konrad and Szelenyi, 1979) which is systematically suppressed. Large-scale sociological surveys (e.g., on living conditions of the working class) and opinion polls represent a shift in knowledge production on Communist societies.

A relative political liberalization of the 'Thaw' and reformist movements of the 1960s enlarge the scope of academic discussions, and increase the participation of social scientists in public affairs and policy-making. Reformist governments seeking to modernize the economy engage various social scientists, especially economists, as scientific advisors and launch public discussions on reforms in the media. Nonetheless the degree of academic freedom and openness varies considerably from country to country. Marxist revisionist currents appear in Poland (the so-called 'Warsaw school of history of ideas'), Hungary (Lukacsian sociologists), Yugoslavia (*Praxis* group), etc. Original theoretical developments are to be found under less constraining regimes or on margins of centralized academic systems. As examples we can cite, among others, works by the Estonian cultural historian Mikhail Lotman and the Tartu–Moscow Semiotic School, Polish sociologists led by Stanisław Ossowski.

A special status of economists is to be stressed: they are not only the largest discipline in terms of university chairs, research institutions, and staff, they are often given a greater intellectual autonomy, due to the crucial role of economic performance in the competition of Communist and capitalist systems. Economists grow to political influence in their respective countries, in particular, during the economic reforms of the mid-1960s (Wagener, 1997). Works by East European economists (especially Hungarian and Polish) on market socialism find an echo among Western neoclassical scholars (Bockman, 2011). Along with the Soviet school of optimal planning (led by the 1975 Economics Nobel Prize winner Leonid W. Kantorovitch), substantial contributions are made, just to mention a few, by Oscar Lange, Michal Kalecki, and Włodzimierz Brus (Poland); János Kornai and Peter Thomas Bauer (Hungary); Branko Horvat and Jaroslav Vanek (Yugoslavia); Ota Šik (Czechoslovakia).

During the 'Thaw,' international contacts and cooperation across the Iron Curtain are intensified, especially in strategic domains (applied mathematics, space, computer science, economic development, and so on). Groups of American and European specialists, as well as individual visitors, are admitted to the Soviet Union and other countries of the Socialist bloc from the late 1950s. Western scholarship becomes partly available through scientific journals and translations of seminal works (e.g., the Russian translation of "Economics" by Paul Samuelson is published in 1964), but it has a restricted circulation. The international mobility of Soviet and other Eastern European scholars is also limited and is mostly open to Party members and officials. Contacts and moves of foreign visitors, in turn, are strictly controlled and surveyed. In 'soft dictatorships,' like Poland or Hungary, international exchanges are much more intensive: social scientists (especially economists) are allowed to participate in international conferences abroad and to visit Western universities as invited fellows for longer stays. Student exchanges and other forms of scientific cooperation are frequent. For instance, an international research project on the impact of industrialization on everyday life carried out in mid-1960s in 10 countries, funded by United Nation Educational, Scientific, and Cultural Organization (UNESCO), is directed by the Hungarian sociologist Alexander Szalai. Economists from Hungary, Yugoslavia, and Poland are engaged by international organizations in programs of development in the Third World. In other cases, as in the USSR, Romania, or the GDR, social sciences mostly remain in isolation.

In spite of the intellectual revival and intensive institutional development during the 'Thaw,' newly established social sciences are in a precarious situation until the end of the Communist rule. With the return of a conservative trend after the Prague Spring and the Soviet invasion in 1968, the contraction of academic autonomy and repressions against ideologically dubious 'revisionist' social thinkers are renewed in many Socialist countries. Especially, sociology falls once again in disgrace (except in Hungary or Bulgaria where it develops without interruption). For instance, in the Soviet Union a newly created Institute of Concrete Sociological Studies is closed in 1972. The antirevisionist and anti-Semitic campaigns are followed by a new wave of social scientists' emigration to Western Europe and the United States. Previous developments continue to exist as a 'shadow science' in a form of *samizdat* publications and informal seminars (Keen and Mucha, 1994; Koleva, 2002).

One should wait for Perestroika and the fall of the Berlin Wall for scientific internationalization and political liberalization. In the atmosphere of 'stagnation' (the years of Brezhnev rule from 1968 until mid-1980s), the purity of ideological-theoretical basis is controlled by Party censorship. Some Western scholarship (Parsons' functionalism in sociology or some neoclassical economics) is tolerated, but only if it is reinterpreted along the 'right' ideological lines and to the extent to which it is 'useful.' In order to cope with this ideological pressure, SBS scholars develop different strategies: the use of a special language full of euphemisms, and the ability to read 'between the lines'; the predilection for mathematical formalization and 'pure theory'; the technocratic language of statistics; or a retreat to politically neutral subjects (e.g., a history of prerevolutionary doctrines). As a result of censorship and self-censorship, social sciences – caught between the theoretical dominance of Marxism–Leninism and technicalities of applied research – are hardly able to develop original theories, especially middle-range ones, of Socialist societies. This legacy still persists in social sciences even after the fall of the dictatorial regimes where the autonomy of scholars remains an open question (Bikbov and Gavrilenko, 2002–2003).

Latin American Military Dictatorships

Contrary to Eastern Europe, monographic studies on national disciplinary cases are rare and limited to bigger countries (as Argentina, Brazil, Chile, and Mexico), while comparative analyses are frequent. Several systematic comparisons have examined the autonomy and institutionalization of SBS (Brunner and Barrios, 1987; Calderón and Provoste, 1992; Sonntag, 1988; Trinidade, 2007). An overwhelming majority of comparative books on the subject are published, thanks to foreign support (Canadian International Development Agency, Ford Foundation, UNESCO, and Maison des Sciences de l'Homme).

If compared to the Socialist bloc, a greater variety of experiences in political regimes and SBS institutionalization patterns characterizes the twentieth-century Latin America. Dictatorships were frequently responsible for the SBS instable development, but not necessarily: some nondemocratic governments were SBS friendly, while some democratically elected regimes suspended their development. In this complex twentieth-century SBS history, the 1970s mark a turning point. SBS achieved a certain level of institutionalization, at the same time, many Latin American countries experienced waves of bloody repressions. Most recent dictatorships have often had deep consequences for social sciences persisting today.

Politics and SBS before the 1970s

The transition of most Latin American societies to democracy and modernity was not exempt of deep tensions, which manifested themselves in acute social conflict and political instability. Chile, Colombia, Uruguay, and Venezuela constitute the few exceptions on the continent: a relatively stable political party system, peaceful succession of governments, and opposition tolerance were achieved here long before the 1970s.

The expansion of State intervention following the global crisis of the 1930s gave a powerful impetus for the development of SBS disciplines, especially economics and demography, in México, Brazil, Argentina, Chile, Peru, Colombia. Afterward, the trajectories of social sciences were affected, though unequally, by multiple dictatorial regimes experienced by these countries. Having dissimilar political histories, Mexico and Brazil both provided a steady growth for SBS in public institutions. Mexican one-party dominant system, established after the 1910 peasant revolution, let the *Partido Revolucionario Institutional* monopolize the access to presidency for 60 years. Relatively tolerant to public opposition, Mexico was particularly SBS friendly. Continuity for SBS was also strong in Brazil, even if its political system was less stable. Open elections and civil rights were fairly respected until a new military intervention of 1964–85. In both cases, humanities and social science were associated with national identity and mainly reserved to social elite members. Both countries kept most SBS activities in public institutions and developed distinguished academic centers supported by the State as El Colegio de México or el Museu Social de Río de Janeiro.

Argentina is probably the most extreme example of tensions between democratization and order. Between 1930 and 1983, Argentina saw a succession of civilian and military governments and experienced periods of restrictions on free speech, free assembly, and participation in government. In spite of the massive enrollment of students and academic freedoms, Argentinian public universities suffered from underfunding and recurrent political purges (Buchbinder, 2005). Academic instability prevented specific and legitimate hierarchies to be established and reproduced. 1930 and 1943 dictatorships as well as Juan Domingo Perón's (1945–55) elected government faced new conflicts. Overwhelmingly supported by the masses, but close to Catholic Church and reluctant to universities' autonomy, Perón caused the dismissal and exile of numerous intellectuals and scientists. Amado Alonso (Spanish philologist, future professor, and PhD honoris causa at Harvard University), Bernardo Houssay (future Medicine Nobel Prize winner), Raúl Prebisch (the most famous Economic Commission for Latin America economist) left the country (Buchbinder, 2005, p. 149). Purges did not cease after Perón's overthrow. Those who had lost their positions in public universities came back and expelled those who had arrived later (Neiburg, 1998). Yet, the 1955–65 decade, governed alternatively by civilians and military officials, is considered to be the golden age for SBS in Argentina: new disciplines as psychology, sociology, and economics were created; many positions were opened; university budget increased; the national research council (CONICET) was founded; State agencies recruited many SBS graduates. The modernizing process was interrupted by a new military coup in 1966 that punished especially natural and social sciences. While many scientists and artists left Argentina, those who stayed in the country became closer to Peronists and leftists' parties and radicalized their positions denouncing the alliance of armed forces, social elites, and imperialism.

Despite political diversity, certain common features can be mentioned in the development of SBS in Latin America. On the one hand, as in Eastern Europe, political elites expected from SBS empirical data and useful tools to improve population and territories' management. On the other hand, this ambition was highly supported by international organizations and especially by American foundations since President Kennedy proposed the Alliance for Progress (1961) as a kind of Marshall Plan (1947) for Central and Southern America to prevent Communist expansion in the region (Berman, 1983; Smith, 1991).

Geopolitical concerns and international funding were then at the very origin of the institutionalization of social sciences, but also of their regionalization. US support to Latin American SBS was not exempt of competitors and conflicts. The Communist Party's network, the Catholic Church and European governments were also involved in Latin America to promote different styles of social thought. In 1964, the 'Operation Camelot' became a scandal in Chile, revealing that area scholars, supported by US Army, were supposed to gather information relevant to the US counterinsurgency program (Navarro, 2011). But, for many decades, US influence was indirect. Three main regional organizations, all of them financed by international funds, contributed to the expansion and regionalization of SBS: the United Nation Economic Commission for Latin America (ECLA, created in 1948, mainly composed by economists), the Latin American Faculty of Social Sciences (in Spanish FLACSO, created in 1957, with a main participation of sociologists and political scientists), and the Latin American Council of Social Sciences (in Spanish CLACSO,

created in 1967, with a similar composition). In this context, there was a competition among countries and institutions to attract international support as well as a rivalry between universities and international organizations to keep SBS under their scope (Beigel, 2013).

ECLA gave Latin American SBS a clear mission: development's promotion and technical support. ECLA's founding father, Raúl Prebish, stressed the opposition between the 'center' and the 'periphery,' focusing on the international division of labor based on degrees of industrialization. Between 1950 and 1970, many issues and analytical categories were developed in strong collaboration among Mexican, Chilean, Argentinian, Brazilian, Uruguayan scholars (Love, 1996; Sonntag, 1988) but also with American and European contributions. The structuralist inflation theory (in economic sciences), labor informal sector analyses (in sociology), or bureaucratic authoritarian regimes' conceptualization (in political sciences) are just three main examples of Latin American themes that gained international prestige.

As most of SBS formation was offered in public universities, placed in the core of main cities, open to ideological diversity and with highly politicized students, powerful students' association appeared and made of universities one of the most important social actors in the region. Contrary to technocratic organizations, universities and in particular students associations were closer to critical approaches and frequently to Marxist theories and Communist parties. Some authors conclude that vigorous commitment to social causes and personal engagements with leftist parties were sometimes a more important source of prestige for SBS professors than originality and intellectual strength. Even if students' politicization came earlier in some countries (Argentina and Peru) and later in others (Chile and Mexico), by the 1970s, youth was a crucial factor of Latin American political dynamics.

1970s' Dictatorships and Their Legacy for Latin American SBS

After the Cuban Revolution, a New Left was consolidated in the region, having strong ties with universities and SBS. The clearer expression of academic radicalization was the emergence of the 'dependency theory' that, contrary to the ideas originally promoted by ECLA, accused Western imperialism of the region's underdevelopment (Love, 1996). While SBS scholars in the 1960s invested most of their energy in creating and extending public agencies, a decade later many of them concluded that these efforts were useless without a revolutionary break of imperial ties. Universities were main participants in political mobilization and radicalization. Their students were frequently involved in the emergence of urban and rural guerrilla in Argentina, Bolivia, Brazil, Chile, Colombia, and Peru. Most 'dependentist' scholars (sociologists, economists, historians) had a political engagement in the 1960s.

Even before the military coups, SBS were already victims of violence. Urged by the imminence of revolution, teaching and research activities were subordinated to political commitment. Face to growing mobilization and radicalization of their students, many scholars left public universities behind to create private research centers. Tired of facing threatens and mistreatment, many specialists associated themselves to form a sort of cooperative in order to share a working space and fight together for foreign or private financial support. At the same time, those intellectuals that remained in public universities were often the first victims of paramilitary assassinations.

Due to SBS previous development and Pinochet's government extreme methods, Chile was the most dramatic example of the destructive effect of dictatorships. The fall of Santiago de Chile as a cultural center had deep consequences for the previous regionalization of social sciences. ECLA and FLACSO did not disappear but lost most regional importance and political influence. Due to the reception of refugees, Mexico gained a certain importance in SBS production during the late 1970s and the early 1980s. Accompanying its economic importance, Brazil strengthened its regional scientific relevance, especially in anthropology. Nevertheless, a direct link was established between Latin American scholars and American and European universities. As refugees first, young scholars started following their degrees abroad with no relation to their universities of original attachment. In economics, US dominance was therefore unquestioned. In sociology, the competition between US and European academies remain stronger even today.

Locally, Chile experienced as Argentina and Uruguay an unprecedented violence. Universities were put under surveillance and dictatorships' designated authorities concentrated most prerogatives and were entitled to purge students and professors. Many of them were kidnapped from university locals. Most were executed after 'disappearing.' A few were formally arrested and spent many years in prison or fled the country. Others were fired without explanation and excluded of any public institution of teaching and research. In Uruguay, 40% of professors lost their jobs. Many public research centers as the Uruguayan Instituto de Ciencias Sociales were closed. In many Chilean and Argentinian universities, SBS degrees in sociology, psychology, and anthropology were suppressed or no more inscriptions were accepted. In Chile and Argentina, students' enrollment dropped drastically (Brunner and Barrios, 1987, p. 45). Even libraries were purged of texts written by Marx, Freud, and Einstein as main references of ideological deviance. Less studied, Bolivia, Peru, and Paraguay suffered similar processes once 1970s dictatorships were established.

At the same time, dictatorship caused or reinforced the migration of SBS from public to private institutions (Brunner and Barrios, 1987). The most significant and generalized legacy of Latin American dictatorships was the creation of private research centers disconnected from teaching activities. Considering the importance and stability of public institutions in Brazil, private centers were fewer but produced the most innovative and prestigious research. During dictatorship, these centers exercised a very discreet activity, 'for their own.' Participants experienced these years as working in a 'catacomb university.' In fact, the separation of teaching and research was encouraged by foreign donors and by governments. On the one hand, private centers could only survive, thanks to the symbolic and material support by international organizations. On the other hand, dictatorships' attention was focused on universities and students' belligerency. Studies produced in the private centers were not particularly visible or disturbing.

This migration from public to private research centers had consequences in SBS production. General theory was abandoned in favor of more concrete and specialized studies. Certain themes related to international concerns grew while

others, focused in national reality, regressed. Policy evaluation and counseling were encouraged while descriptive and interpretative approaches declined. Critical intellectual profiles were put at a disadvantage while technocratic orientations were recompensed.

Dictatorship action was not only repressive though. Military governments had an active role in reformatting high educational system. In Chile, Pinochet policy left a persisting legacy: on the one hand, public universities declined; the cost of education was taken as a private responsibility; on the other hand, competition for funding was encouraged among institutions to improve their efficiency. In Argentina, military policy withdrew economic resources from public universities located in big cities to invest them in geographically dispersed research centers. At the same time many prestigious SBS researchers were fired from the CONICET, many right Catholic intellectuals without any academic recognition were recruited or designated by national authorities.

Mexico and Brazil were also touched by SBS political radicalization. The 1968 Tlatelolco square massacre was the most extreme expression of Mexican repression of students' protests. During Brazilian last dictatorship, many students were persecuted, imprisoned or killed. But compared to others, these repressions were pretty selective, and most SBS organization and programs not only survived but also were enlarged (Brunner and Barrios, 1987, p. 42). University autonomy was respected and professionalization did not stop. Since Santiago de Chile declined as a center of SBS excellence, Mexico and Brazil consolidated their influence by receiving first Latin American refugees, students, and scholars later.

As in Eastern Europe, various social science disciplines did not receive an equal treatment depending on the ideological bases of military governments: liberal in economics and mainly Catholic fundamentalists. Sergio Castro and Adolfo Diz were appointed economy minister by Pinochet in Chile and President of the Central Bank by Videla in Argentina respectively. They were accompanied and followed by many US trained economists in the highest state positions. At universities, economics flourished while other disciplines decayed. While leftist economists left public universities for exile or private research centers, liberal economists founded private schools or think tanks collaborating with the military. At the University of Buenos Aires, the degree in 'political economy' was changed into 'economics' and its curriculum was deeply modified to enlarge mathematics and reduce humanities and social sciences. In the long term, dictatorships encouraged a strict delimitation between economics and other social sciences that persists today. While most economists became international and private consultants independent from universities and public agencies, academic institutions, especially public ones, employ most other SBS scholars.

Contrary to more stable democratic nations, certain aspects of previous SBS configuration still remain: the disconnection between excellence in research and teaching, the contrasting sort of economists and other social scientists, the preference for applied studies, the importance of private and international funding for private research centers, the fragmentation of national fields, the importation of general theories and international prestige as a source of distinction due to weakness of other national and regional sources of academic recognition.

Conclusion

In all dictatorships, the intellectual and institutional *autonomy* of SBS is compromised, though to different degrees and in different aspects. Inasmuch as immediate needs of dictatorial regimes are privileged, SBS scholars loose their capacity of freely choosing their subjects and, frequently, their methods. As authorities try to control public discourses, academics loose their right to diffuse publicly their findings or views. A perpetual threat of repressions and dependence on public authorities prevent from the consolidation of autoregulated academic communities and reinforce their fragility vis-à-vis external influences. Nonetheless, one should not overestimate the *specificity* of SBS in dictatorial (autocratic) regimes as compared to democratic ones. The predominance of empirical (statistical) forms of knowledge and orientation toward public policy needs characterizes, to a lesser or a greater extent, relations between the state administration and academia in democratic countries during the twentieth century.

Most common and important features of social sciences under Socialist regimes are as follows: ideological alignment to historical materialism (Marxism–Leninism) under control of censorship; political guidance with respect to legitimate objects of research and theories; hesitations between practical needs (rationalization of government) and fear of dissidence; technocratic and applied orientations of social sciences; a relative isolation and autarchy; auto-limitation in theoretical activity. However, practical and ideological needs of the Socialist states contributed to professionalization and institutionalization of social sciences on a pace with democratic countries in the post-World War II period. Privileged relations with political authorities could enlarge the marge of initiative and autonomy, yet this autonomy was always threatened. Post-factum (or by external observers) SBS under dictatorship are often considered as 'antiscience,' 'pseudoscience,' or 'ideological bluff' like political economy of Marxism–Leninism or Nazi sociology (Lepenies, 1985). A forced compromise with authorities and official ideology was also often a source of a poor public image of social sciences. Nonetheless, an important role of social scientists in the reformist movements across the Socialist bloc is to be stressed. Humanistic and critical discourses, gestated in the liberal atmosphere of 'Thaw,' reappear with force at the moment of Perestroika and democratic transitions.

Latin American dictatorships also show common patterns with regard to SBS: violence and repression against public institutions, persecution of students and intellectual networks; ideological intolerance to critical discourses in public space; indifference with respect to legitimate objects of research and theories apart from economics and religious controversial matters; technocratic and applied orientations of social sciences; strengthening of international networks at the expense of regional and national integration; privatization of research. Similarly to the Communist Eastern Europe, practical needs of the Latin American states contributed to professionalization and institutionalization of social sciences. But unlike in the former, neoliberal policies and internationalization were encouraged here well before the fall of dictatorial regimes. Budget cuts and suppressions of positions in public institutions were specific factors of SBS' economic and symbolic

dependence. On the other hand, international networks were a source of economic and political support for SBS scholars. International connections, social knowledge, and commitment to free thought gave SBS a crucial role in reformist movements and democratic government in the 1980s.

Yet, academic freedoms and self-regulation are never wholly achieved; furthermore, new challenges are faced by social sciences. A shifting situation of SBS alone might be viewed as a good barometer of social and political change in post-dictatorial societies.

Social and Economic Change: Psychological Challenges for Individuals

Rainer K Silbereisen, Center for Applied Developmental Science, University of Jena, Jena, Germany
Martin J Tomasik, University of Zurich, Zurich, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although the consideration of contextual influences on individual development has a long tradition in psychological science, the rapid pace of social, economic, and political change around the globe has spurred new conceptual and empirical research on the dynamics between macro-level change and individual-level adjustment and development. This research is targeting epigenetic, psychological, and social processes by various methodological approaches, such as analysis of archived data, cohort comparisons, natural experiments, comparisons between stages of social change, or the assessment of interindividual differences in response to challenges arising from social change. Empirical findings from different methodological approaches converge in the notion that social change has both comprehensive and polyvalent effects that often follow a prototypical syntax and cascade through the various levels of developmental contexts, which mediate the effects on the individual and moderate them as a function of cultural traditions. More recent research shows that individuals differ in the extent to which they are affected by such change and that these differences are in part attributable to the way demands resulting from social change are perceived and appraised, to how individuals cope with such demands, and to the moderating effects of proximal and distal developmental contexts.

Social change is an umbrella term for various kinds of radical and comprehensive changes concerning the political system of a society, its economic organization, major social institutions, means of production, demographic composition, ecology, and value and belief systems. While social change is obviously not a new phenomenon, many believe that the pace of social change has been accelerating over the recent decades (see Tomasik and Silbereisen, 2012). This acceleration may be rooted in the growing integration of societies across the globe, thereby facilitating the spread of innovations; or it may be due to actions by political elites in less developed countries who want to catch up with technologically more advanced societies.

Until 20 years ago, social change was not a prominent topic of empirical psychological research, but this changed with the breakdown of the Soviet Union and other communist countries around 1990 in Europe and Central Asia. Although this started as a purely political transition, it soon turned into a broadscale economic transformation to market capitalism, with all kinds of concomitant adversities, such as increased unemployment and income disparity, despite many beneficial effects. The effects of the political breakdown were also soon overlaid with new challenges of globalization, which changed traditional means of production and removed many trade barriers resulting in worldwide competition. Formerly protected markets had to open up for products manufactured by cheaper labor, for migration of people from different regions of the world, and for unprecedented idea diffusion around the globe. The large-scale change processes were further influenced by the worldwide financial and economic crisis that started in 2007 with the collapse of global bank systems. This lead to entire regions suffering from economic depression and recession and to a currency crisis in the European Union that is still unresolved. Many countries also had to make major adjustments to their already strained welfare systems due to challenges resulting from demographic change, such as a decline in the birthrate and an increase in the older segment of the populations. Another challenge is the increase in migration across borders with permanent resettlement, as well as transnational migration characterized by belonging to more than one nation-state.

Concerning the causes of the macro-level changes, many explanations have been offered. If we take the breakdown of the communist rule in the former German Democratic Republic (East Germany) as an example, and this may as well apply to other countries dominated by the former Soviet Union, a prominent theory sees the lack of modernization of the entire society as core element behind its collapse. This was compounded by an inept model of central planning of economic activities that were completely out of step with the needs of an industry dependent on innovation and worldwide cooperation. Likewise, modern modes of production require increased autonomy and responsibility, and in response to that politics have to exercise participatory modes of governing. Other explanations have suggested that it was not the state of the economy that was pivotal in the downfall of communist rule but a basic discrepancy between the declared humanistic beliefs of a society and a permanent deprivation of civil liberties. Such discrepancies were made visible to growing segments of the population by the increased interconnectedness of people especially via new means of communication such as internationally broadcast TV programs. It is interesting to note that countries such as China are now struggling with similar problems related to the Internet in spite of the new freedom in the economy and business.

Psychological Dynamics behind Political Change

From a psychological perspective, a rapid transformation of the political system is not possible without a parallel radical decline in the population's support of the status quo. Under ordinary circumstances, people tend to engage in various motivational psychological processes aimed at defending the social system in which they live, even when confronted with

massive failures in its functioning. This seems to be because we all live interdependently in broader social systems and have a tendency to uphold the legitimacy of whatever norms, rules, and social structures inherent in these systems. However, according to the systems justification approach, there are circumstances demonstrated in experimental research that modify this general tendency. External threats to a political system tend to strengthen the justification of the established order, and people typically defend systems on which they depend, often in spite of criticisms they themselves may have. Another condition that strengthens the justification of an established order is the inescapability of a political system, be it through tight border controls or through other constraining measures. Similar to the system justification approach, one can also delineate conditions that lead to collective action in situations of social change, among them the erosion of intergroup barriers that are seen as unjustified.

The aim of such motivational processes, as evidenced by the case of the former communist countries, is a rationalization of the situation in order to make the experience tolerable; here other new research has demonstrated that rationalization of constrained freedoms (seeing them in a most positive light, as suggested by systems justification) rather than taking action (protesting openly) against such circumstances is related to the severity of personal restrictions. The difference probably lies in the level of absoluteness – if the restrictions to freedom apply to all in a complete, certain, and permanent fashion, rationalization is the likely response. If, however, restrictions do not apply to all equally, or are uncertain, and time-limited, then behavior to the opposite of system expectations is more likely. Note that such psychological reactance was promoted by changes in the border regime, and by otherwise increasing contacts between East and West in Germany and elsewhere. The unexpected opening in 1989 of escape routes to the West through neighboring countries, such as Hungary, reduced the tendency for system justification among the East German population.

Finally, a lack of control over one's personal life is often compensated by a belief in the control established by the social system. In other words, commonly shared stability mechanisms may keep a system alive for a long time, but the tipping point may be easily reached once the system's legitimacy is put into question. This is probably what happened with the unprecedented civil strife shortly before the fall of the Berlin Wall because ways to escape, to become less dependent, and to exercise control had become evident. The decline of the ideological barriers of the Cold War also played a role in reducing the external threat. In other words, a major contribution to the openness for social change by the people and in part by the elites of East Germany was due to the gradual erosion of the motivational forces to maintain the status quo and by the promise of reforms that, however, came too late. The failing of reforms had undercut the reality and perception of the absoluteness of all social controls that had helped to stabilize the system by motivational processes. Such processes may also, of course, be contagious – the awareness that absolute political systems similar to their own have been toppled may lead citizens to question the absoluteness of their own system, thereby empowering them to vent their accumulated anger over the failure and injustice of their own system and increasing the likelihood of collective action toward social change.

Social Change a Topic of Psychological Research

Psychology was badly prepared to studying the consequences of macro-level change on individual behavior and development. When we conducted one of the first studies on the consequences of German unification, the issue of social change and related concepts did not really exist in the psychological literature. For example, entering the key words 'social change and well-being' in the PsychINFO data source returned 29 entries up to 1998. The same search from 1998 to 2012, however, returns 219 entries, which represents an impressive increase in research-based activities. As is understandable in a situation of unpreparedness, researchers in psychology fell back to earlier approaches that had stressed the role of the physical and social environment, such as Bronfenbrenner's model of hierarchically organized layers of contexts, from the macro level of societal beliefs via more intermediate contexts such as neighborhoods to the micro context such as the work place or the family and their intersections. Oishi and Graham (2010) see the emerging research on social change since the 1990s as a push to revitalize buried theoretical traditions in psychology that deal with macro-level phenomena in research on human mind and behavior. They deem this as especially true for cultural psychology and its dealing with symbols, meanings and regions, and for social ecology, studying physical, societal, and interpersonal environments. Scientists such as Bronfenbrenner or Markus and Kitayama are seen as utilizing approaches leading directly to research on social change. One has to bear in mind, however, that the contexts, whether cultural or ecological, were traditionally conceived as rather stable entities, whereas social change is by definition a dynamic phenomenon.

The renaissance of socioecological approaches and their transdisciplinary nature comes at a time of another major development in psychology – that of molecular genetics research. As it turns out, both have unique relevance for our understanding of the role of social change and human behavior and its course across the life span. Recent innovations in molecular genetics research for the first time illuminate the actual ways in which the environment influences future psychological pathways, especially through influencing major physiological systems highly relevant for adaptation. More specifically, particular environmental pressures typically related to strains involved in macro-level adversities, such as wartime famine on mothers and their small children (Heijmans et al., 2008) have the capacity to change the expression of DNA via methylation and other molecular processes. They modulate the 'readability' of genetic coding, and thereby influence systems such as the hypothalamic-pituitary-adrenal (HPA) axis that leave a mark on how individuals deal with strain and stress. Certainly such epigenetic influences are not the only ones, and their influence may be moderated by later experiences, but the knowledge that there is a clear biopsychosocial pathway linking adversities typical of social change with individual behavior and development is new. Very recently, researchers also reported evidence that such processes are not limited to childhood.

The role of the stress system is central in the 'experiential canalization' model presented by Blair and Raver (2012). Here, adversities are seen as a source of characteristic restrictions of parenting that translate down to gene expression, and consequently regulate the stress system that is adaptive to the harsh environment being experienced. This leads to a particular pathway of psychosocial development; first by influencing neural connectivity and then by having an effect on behavior core for adjustment, such as self-regulation. The canalization model not only demonstrates ecological mediators (parenting in this case) and biological processes (epigenetic influence of stress system), but also makes an important distinction between short- and long-term effects. The possible negative short-term effect of adversity-stricken environments on self-regulation represents not a deficit, but actually an adaptation to the circumstances that provides benefits by a faster response to threats typical of the environment. In the longer-term, however, such benefits may turn into disadvantages concerning physical and psychological health, if they are not compensated for by benign future experiences.

For psychological concepts on the effects of macro-level social change on individuals, when taken together, the important message of the two strains of research is that the actual experiences of social change, processed through various ecological contexts, are crucial because they leave their traces on core physiological and neurological systems that relate to the ways in which people deal with challenges in general. Against this backdrop it is no big surprise that ways of coping with stress and related concepts play a core role in psychological research on social change.

Lessons Learned from Research on Social Change and Human Development

Studies on political and economic change over the last two decades established a number of empirically validated principles concerning change itself and its consequences for human behavior and development. Considering these results helps psychologists to see how this is embedded in broader societal structures and to understand its dynamics.

Syntax of Change

A good example of the syntax of change is that of German unification. During the transition period following unification, almost all institutions, from welfare to industry, were remodeled after the West German prototype. Several years into unification, however, it became clear that, for instance, the former provision of day care for workers' children actually on the premises of industrial plants had the beneficial effect of attracting skilled workers and their families to the East. More generally, what at first glance appeared to be lack of differentiation between state and economy under the old system, gradually became seen as a possible model for the family-friendly organization of work contexts. In general, the subsequent transformation period was characterized by a renaissance of early child care as a right for all families with children. In essence, such processes can be seen as adaptations – for better or for worse – to 'overshooting' changes of old institutions in the heat of transition.

Role of Cultural Traditions

Cultural traditions built up over decades or even centuries significantly moderate the effects of gross changes in political and economic systems. Same-aged young people who had attended the same secondary school system in the Soviet Union strove quite differently after the breakdown of communism and the Soviet Union if they were raised and now lived in the new Baltic States or in one of the former Central Asian republics. Entrepreneurial skills and activities that, given its history, were traditionally more prevalent in the Baltic States helped to overcome the meanwhile obsolete career paths typical of the Soviet Union (Titma and Tuma, 2005). Similar observations were made by economists who found that old centers of innovative industries quickly became revitalized after German unification. There are many more instances of the role of buried cultural traditions and their revitalization in periods of radical social change, such as the renaissance of Confucian beliefs in Vietnam or the lasting influence of the collectivist cultures in leisure patterns of the young in India's urban middle class that otherwise changed a lot due to industrialization and the effects of globalization. Religion and spirituality also played a prominent role in the breakdown of the (outspokenly secular) Soviet system in Central and Eastern Europe when apparently forgotten orientations and networks came back to life. In cases such as Poland, the church even belongs to those who replace the old elites.

Cascading Effects

Changes on the macro level do not affect individuals directly. Rather they 'cascade down' through various intermediate contexts, ultimately exerting an effect on families, which can be seen as the micro context par excellence. From there, the effect reaches individuals, who are also influenced by their current stage in the life span. A perfect example is provided by research on the effect of social change in a remote valley in Asia (Axinn et al., 2011). Government activities to develop the region by building streets to attract economic development did not immediately change the role of women and the nature of parenting in the traditional communities. Rather, it was the establishment of small workshops that provided paid work and required women to stay outside their homes for the working day. The new experiences had an effect on the appreciation of values such as autonomy, and this then gradually reshaped parenting priorities and also the partnerships toward more equality.

Comprehensive Effects

If radical and comprehensive enough, challenges will have an effect on social, human, and financial capital. In the case of the social change in Europe that followed the upheavals of 1989, it was obvious that people trained in occupations that had been functional under the old system were having difficulties in utilizing their skills, especially in areas like economics and law where qualifications were based on a different value system.

Consequently, such people risked their status within society, because both old and new systems very much based social status on formal educational merits and occupational prestige that, however, were different. This devaluation of human capital, however, did not leave all people helpless, as research by Titma and Tuma (2005) revealed. In the early years after the collapse of the USSR personal agency was found to be more relevant for life success rather than formal qualification or credentials. An example of such agency was the informal selling of scarce but sought-after consumer goods that was based on earlier social ties and that required a high level of personal self-efficacy for success. It was only later in the process, once the new institutional order had been established, that education and other formal credentials became relevant again for one's position in the status hierarchy. It appears that self-efficacy established before the transition even helped people who were close to the former state and party organizations and who subsequently often experienced discrimination and social alienation. Furthermore, since the collapse of the Soviet Union in the late 1980s, there has been a common trend in many postcommunist transition societies toward increasing income inequality, whereby large segments of the population live in poverty while others have become extremely wealthy. In contrast to the 'Kuznet curve,' which posits a natural cycle of economic inequality driven by market forces during social development and transformation, in these postcommunist countries inequality did not decrease even after initial growth. For instance, metropolitan centers gained relative to rural areas, the financial sector increased at the expense of others, and in some countries even expenditures in education and science declined compared to previous times, with negative long-term effects for competitiveness. Overall, these effects are counter-productive for people's trust in the social system.

Polyvalent Effects

Political and economic change is polyvalent concerning consequences for individuals. Therefore, in order to structure possible outcomes for human development, it makes sense to look at the basic tasks and achievements that characterize any particular phase of the life course, often called developmental tasks; in the following, we take young adulthood as an example.

Social change has the potential to affect the ways and means by which individuals resolve the task of embarking on an occupational career, of starting a family or partnership of their own, or becoming an active member of civil society. A review of relevant research have shown that it is not usually the substance or appreciation of the developmental tasks that are affected by social change, except perhaps for the new role of public self-presentation in modern mass media, but that the accustomed steps toward those goals may lose their relevance in the changed societal structure (Tomasik and Silbereisen, 2012). For instance, the combination of high unemployment rates in many countries in Europe, especially those considered to be in transition and the effects of globalization-related adjustments, such as downsizing or unstable work (unemployment rates among young people have reached 40% in some Southern European countries), makes it difficult for young people to follow settled routines for establishing themselves in an occupation. This has negative carryover effects on partnering and family formation, as well as on civic participation. Beyond the effects of social change on core developmental tasks, there are also overarching consequences for people's well-being. In this regard, mental health is of utmost importance for social policies, and it is fair to say that 'threatened well-being,' including an increase in mental disorders, seems to be characteristic of European transformation countries after 1990 (Orosa, 2012). It should be noted that the increase was especially steep in new countries of the European Union, thereby demonstrating that it is probably not only the shock of the 1990s that fueled the changes.

Conceptual Ways of Linking Macro with Micro

Psychological studies on individual consequences of social change require theoretical conceptualizations that reflect the macro level and at the same time model the interindividual processes in response to the manifestations of the macro change. Thus far, psychological research has followed two slightly different routes concerning the outcomes of interest. First, scientists used the specific psychological mechanisms known to influence a particular target behavior of interest, and reformulated particular models to connect additional exogenous variables or design features reflective of social change. Schoon et al. (2007), for instance, who were interested in career transitions in times of social change, used a model entailing parental social class, and parents' expectations for the young adolescent's school motivation and academic success, their job aspirations, the timing of parenthood, with occupational status in adulthood as outcome. Manifestations of social change were represented by individual material hardship that was increasing due to economic challenges and societal unrest in the United Kingdom at that time. The longitudinal data comprised the period from birth until the offsprings' third decade of life.

Second, rather than relying on behavior-specific models, other researchers used a more general conceptualization of processes likely to have an impact on a wide range of different target variables. Conger et al. (2010) used family material hardship to reflect the macro-level conditions at the time of the Iowa farm crisis in the United States. This crisis was characterized by agricultural recession, which included farm bankruptcies, out-migration, and even increased suicide rates. The authors assessed an intraindividual cascade of processes from perceived economic pressure to coping reactions with these strains, resulting in parental distress, marital conflict, and reduced emotional investments, which then hampered academic achievement and social competence in children. The study comprised longitudinal data spanning three generations.

Using these two studies as illustrations serves another purpose – both refer to the landmark research of Glen Elder that he conducted on the Great Depression of the 1930s. He used data from the period but based his work on current concepts (Elder, 1974). This general approach, which characterizes both studies reported, used a circumscribed but potent manifestation of the societal challenges, embedded them via sample and exogenous variables in the larger historical context, and capitalized on established social and developmental psychology models of the target outcomes of interest. To date,

research following such approaches has concentrated on the structure of the life course (timing and sequence of transitions), subjective well-being and mental health (especially interesting because of its dual nature as antecedent and consequence of thriving and success in life), career development, and civic engagement (because it may represent the seed for future collective action to overcome the negative effects of social change). Several other classes of behavior and development were also tackled, such as participation in the new media or leisure in general, but the common denominator is that 'ultimate' outcomes were chosen that are of high relevance for social policy planning (Orosa, 2012).

Methodological Approaches

Closely connected with the conceptual models are methodological approaches, of which four stand out as being the most utilized. First, archived data were analyzed representing cohorts that stand for a historical divergence in macro-structural conditions. The work of Schoon et al. (2007), who used the longitudinal British Birth Cohort Studies of 1958 and 1970, is a prime example of such research. In comparing results between cohorts later in adolescence and adulthood, Schoon could show that personal agency factors, such as job aspirations and educational performance, played a different role in predicting occupational development, depending on the economic prosperity the cohorts had lived through during their formative years. In times of economic stability, job aspirations were of prime importance. In economically precarious times, however, it was educational performance that played the main role. This particular divergence reflects the historical changes on the labor market toward higher skill levels based on extended formal education and advance credentials (Hofäcker et al., 2010).

Second, studies, such as that by Kohn (e.g., 2010), used a natural experiment approach made possible by the gradual diffusion of social change across countries. The countries studied were chosen because they represent advancing steps in a process of social change toward market capitalism. The focus of the research, however, was the role of greater opportunities for self-directed work among people higher in the social stratification hierarchy, which had a subsequent positive influence on personality flexibility. This was demonstrated for the United States and subsequently for Poland in the 1980s before regime change. But one difference was found whereby in Poland but not in the United States, workers' well-being was higher than that of managers, mirroring the greater job protection enjoyed by workers in the former communist Poland. This difference changed rather quickly to the U.S. model after the change from a socialist command economy to market capitalism in Poland. The same change – although more gradual – also happened in other Eastern European transformation countries, such as the Ukraine. Thus, the very fact that the position in the status hierarchy corresponds to higher self-direction and personality flexibility appears to be universal, but it was no longer the workers who revealed higher well-being but the managers as is common in the United States and the West more general. Rather limited change against the backdrop of remarkably stable structures and people indeed seems to be an important characteristic of social change in general (Tomasik and Silbereisen, 2012).

A third approach to studying social change was to conduct planned comparisons between given times in the process of a critical event characterizing radical change in a political and economic system, such as German unification. In the early 1990s, Silbereisen and colleagues began such a program with research comparing same-aged, representative cohorts in young and middle adulthood between 1991 and 1996. During that period of transformation, social institutions in the East related to education, training, and career development in general were replaced with ones that followed the West German model. The effect was an increase not only in the importance of individual choice, but also in personal risk concerning employment prospects. Against this backdrop, the research found that following unification, the timing of first vocational decisions was delayed in the East whereas timings in the West stayed the same. In general, the findings demonstrated the influence of social institutions as pace-setters concerning life-course transitions. However, as expected, in areas where there was no structural change or no obvious role of social institutions, such as the age of first romantic involvement, timing did not change.

Fourth, all the methodological approaches mentioned thus far share the view that the social change addressed was so overwhelming that differences in the extent to which individuals were affected by the change are not really relevant. This was an approach, however, not taken by all. For example, an interdisciplinary group of sociologists, psychologists, and economists, working as part of the largest research consortium on social change in Germany after 1990 (SFB 580), focused on people's particular individual experiences associated with and stimulated by ongoing social change. The emphasis of the psychologists' work was on the internal psychological processing leading to psychosocial outcomes in response to social change.

Recent Research Using a New Conceptualization

This research of the psychologists in the SFB 580 consortium was guided by the 'Jena Model of Social Change and Human Development,' which puts new 'demands' on individuals resulting from change at the core (see Silbereisen et al., 2010). Demands are conceived as proximal manifestations on the individual level of macro-level structural change. These demands are influenced by a cascade of hierarchically organized contexts in which individuals may find themselves and that may themselves be changed through the influence of social change. An example of this is the 'filtering' of risks for individuals' resolution of major developmental tasks by institutions of the welfare state (Hofäcker et al., 2010). For instance, globalization provides challenges for businesses that are passed down to employees, thereby possibly confronting them with unstable conditions which bring with them uncertainties concerning future planning regarding their work and careers. Such demands, however, are not equally distributed across the population. Whereas in some countries like Italy, seniority protects employees from the more negative aspects of globalization, such as job termination, in other countries like Germany, it is the young who are protected against

unemployment. One consequence of this is the dramatic difference in youth unemployment rates. In the sociological terminology of Hedström and Swedberg (1996), demands represent the 'situational mechanisms' that link structural changes on the macro level to the individual and form the point of departure for psychological processing.

Demands and Well-Being

The Jena group studied the relationship between demands in various domains of life and several indicators of well-being. Large representative samples of people in young and middle adulthood from 77 administrative regions in four federal states of Germany were surveyed. The regions represented distal contexts through which social change cascades to the individual. As reported by Silbereisen et al. (2010), demands were assessed by asking participants to endorse statements concerning growing perceived uncertainties in the domains of work, family, and public life over the last few years. The topics were chosen so as to reflect changes in population statistics for the 5 years leading up to 2005. For example, the item, "When considering the past five years, my career plans were often hindered by unforeseen events and circumstances" was associated with the documented increase in staff turnover rates and other relevant indicators of precarious work conditions between 2000 and 2005. A cumulated load index was formed for six items each that were deemed to cover relevant experiences people could have faced due to the ongoing social and economic change.

Based on the filtering concept, and as expected, participants who were employed, married, had high educational attainment, and were living in the more prosperous West of unified Germany showed lower demand loads. The strongest effect was found for current employment status. Moreover, the 77 regions (identified in official European statistics as NUTS-3 units) also showed differences in aggregate demand loads; a variation that reflected differences in actual economic prosperity. Taken together, the demands indeed seem to reflect manifestations of objective circumstances. What applies to demands in the domain of work also was revealed by family demands (such as "When considering the past five years, it is more difficult, given my present life circumstances, to decide whether I want to have a(nother) child or not").

In terms of resource conservation, demands may bring with them the threat of resource loss in important domains of life and thereby produce stress and require action. Certainly, it is known from relevant research that the anticipation of future possible threats constitutes a potent source of stress which is likely to have effects on well-being if not dealt with adequately. Thus, although demands resulting from social change are not specific events but personal concerns, it is feasible to assume that individuals differ in their experience of uncertainties relevant to their resolution of developmental tasks and to the maintenance of their well-being. Recent research, which focused on the relationship between demands and various indicators of well-being, distinguished between a stable 'trait' component and a variable 'occasion' component of life satisfaction. They demonstrated that demands have an effect on the occasion component of life satisfaction, but that the trait component also has an effect on the demand load; the two effects had about the same magnitude. Thus, demands were confirmed as affecting (reducing) well-being independent of the fact that people showing higher well-being also experienced lower loads of demands.

Negotiating Demands of Social Change

If demands related to ongoing social change mean stress for individuals, then how they deal with it should play a role. To assess these ways, the Jena Model used the developmental regulation approach by Heckhausen et al. (2010), which distinguishes between engagement with the demands (working hard to resolve the issues whatever it takes) and disengagement (to redefine or avoid dealing with the demands all together). For example, an individual when facing impaired career perspectives may undertake many activities and invest a lot of effort into retraining, and yet ultimately decide to turn with all effort to a different field with better chances. According to Heckhausen et al., this represents three forms of engagement in pursuing age-typical goals. In contrast, disengagement means that, when faced with an obstacle to achieving a goal, the individual either downgrades the importance of the goal or makes a total change in direction; both behaviors represent two different forms of disengagement. In the sociological terminology of Hedström and Swedberg (1996), engagement and disengagement represent the 'action formation mechanisms' in responding to social change.

Analyses on the German data, whereby demands were assessed by items referring to the experiences reported, revealed that engagement was always more endorsed than disengagement, and that engagement was greater the more demands were appraised as a challenge, as leading to probable gains, and controllable. Higher demand loads corresponded to higher levels of both engagement and disengagement. All this is what one would have expected from earlier research on very different issues, such as complications of physical health or imminent serious life decisions (see Heckhausen et al., 2010). Whether dealing with demands of work or with demands related to family did not make much of a difference. Participants from the more severely affected East of the country revealed lower levels of disengagement in spite of higher levels of demands than in the West. This finding probably means that these people cannot afford to disengage given the fewer reserves, such as family financial assets or opportunities in general, at their disposal, due to generally lower affluence in the East.

Nevertheless it would be inadequate to view engagement as the best option under all possible circumstances. When the Jena group again looked at the relationship between demands and well-being, it became clear – as expected – that engagement or disengagement has a positive effect on well-being only when the action taken is a good match to the individual's circumstances in terms of controllability. More specifically, well-being was less negative given a certain demand load if people judged the demands to be under their control. It seems that engagement or disengagement not congruent with opportunities is harmful.

Moderating Effects of the Context

Of special importance for the Jena Model is the view that the relationship between demands and psychosocial outcomes is

moderated by contextual variables. A prime example is the economic prosperity of the political-administrative regions within Germany and how this affected the people living there. As already mentioned, the sample was structured by 77 of such regions.

Based on other research conducted soon after unification (e.g., Bergmann, 1994), we expected a weaker effect of demands on well-being in regions with lower economic prosperity. In earlier studies we found that economic hardship in the East of the country was not associated with depressive mood, which was contrary to findings for the West (and for many other samples from Western countries). We saw this protective effect as rooted in differences in attributions of the cause of the problems: system failure in the East, individual responsibility in the West. Such differences were repeatedly revealed in surveys for the 1990s. What the Jena group now found in two related studies for work and family demands (Pinquart et al., 2009) confirmed our expectations and lends extra credence to the ecological-contextual approach in general. Utilizing multilevel analyses, the relationship between demand loads and well-being was less negative than the average among those who lived in regions with high unemployment rates.

In interpreting these results, the 'social norm' effect known from economics comes to mind. This means that the relationship between individual unemployment and mental health was weaker when the aggregate unemployment rate was higher: under such conditions, the unemployed feel better about their situation. It is clear that the demands studied are not equivalent to unemployment, but the norm effect was also observed for precarious working conditions and the work demands assessed came close to that.

We also found that the effects of engagement were less positive in economically challenged regions and that under such circumstances disengagement seemed to be even positive for well-being as response to high demands in economically weak regions. To understand this better, we separately analyzed a subsample of those who were affected by really high demand loads and again compared the 77 regions. As expected, the regression lines between satisfaction with work and disengagement were positive in economically disadvantaged regions and negative (as on average) in the other regions. Furthermore, satisfaction increased over time as a function of disengagement in the economically disadvantaged regions but decreased in others.

Benefits of Social Change

Social change is, of course, not limited to negative effects, although many of the studies we have reported concentrated on that, especially given the economic situation in the mid-2000s. An interesting aspect of globalization-related strains on the job market is that employers often seem to compensate increases in performance pressures by offering potential benefits such as growing autonomy in decision-making. Our view was that autonomy may function as a resource to counterbalance the negative effect of demands, as we found. The negative effect of high demands on subjective well-being was balanced by job autonomy. Other resources such as optimism may also play a role by increasing the likelihood of engagement (see Pavlova and Silbereisen, 2013, who demonstrated that even a rather stable disposition can affect how individuals deal with change).

Generalization across Countries and Type of Demands

Demands are conceptualized as rooted in changes on the macro level, affecting major domains of life not only in Germany but also in other countries that have undergone political and economic change. The level of demands may vary (as the comparison of East and West in Germany already revealed), but the effects should nevertheless show commonalities, also concerning demands other than those related to work and family.

Role of National Contexts

The results reported thus far refer to Germany and show that demands indeed are stressors that affect well-being negatively. Welfare systems work as a buffer against the negative consequences of social change in peoples' life, and in this regard Germany can be considered a conservative welfare regime. It is transfer-oriented and thereby attenuates the economic consequences for employees that, for example, result from unemployment. The current Polish system, in contrast, shows strong liberal elements that put an emphasis on the responsibility of the individual rather than the state (see Hofäcker et al., 2010). Against this backdrop, a parallel research program in Poland, which is a country considerably more stricken by the effect of political and economic change than Germany, gave a first confirmation that the Jena Model can be applied more broadly. Analyses on the ways in which people deal with demands revealed beyond many similarities to the German results, a major difference concerning the role of how demands were appraised: whether they were seen as a challenge or a threat, or as a gain or a loss did not play much of a role in Poland. This is likely a consequence of the much less generous welfare transfers common in that country. As such transfers mount to only one-seventh of those in Germany, people cannot afford to make their engagement with demands dependent on favorable appraisals but have to engage with them 'come what may.' This was the case in spite of the fact that demands were perceived as more threatening, and associated with loss and low controllability. Moreover, people responded to loss by disengagement, probably to preserve strength to tackle the many other pressures in their life.

Current social change has many more aspects than those reported here. For example, research in China focused on the effect of new opportunities for self-realization on parenting and found that parents who perceived the ongoing economic changes as positive reported more encouragement of independence in their adolescent children, thereby helping them to adapt to the new economic situation. This effect, however, was more pronounced in urban regions, whereas in rural areas, similar concerns about demands to those studied in Germany prevailed (Chen et al., 2010). Likewise, in a sample of young university graduates from Ghana, the perception of demands in the work domain corresponded with the intention to continue with education, thereby hoping to be better prepared for the new times.

Demands of Active Aging

A different line of research addresses the demographic shifts resulting from increasing life expectations and the 'active aging' policies pursued in many European countries. People beyond statutory retirement age (65 in Germany) are growingly confronted with demands to participate in life-long learning, to maintain their physical fitness, and to complement their future income after work life from state pensions by private pension insurance. Using the Jena model as before but with demand statements adjusted to the purpose, we analyzed demand levels and appraisals, again looking for effects of the economic disparities between East and West of unified Germany. The results revealed that demands were higher in the East among those still in work, and that demands were appraised as more threatening and less as a challenge than in the West. Among those already receiving a pension from the nation-wide public pension insurance fund, however, differences no longer existed between the regions. In other words, differences still existing in the economic opportunities between the two parts of unified Germany are mirrored in different demand levels. This has consequences for psychosocial outcomes, especially when one takes into consideration that older people's negotiation of demands linked to active aging seems primarily to depend on how they appraise these demands.

Conclusion

The main result of the research reported in this article is the role of various levels of contexts in moderating the complex relationships among demands (and benefits), strategies to deal with reduced opportunities and new expectations, resources one can bring to the fore, and psychosocial outcomes that are crucial for adjustment in life. This relationship varies as a function of the distal or proximal ecology, which provides risks and opportunities, and transforms the challenges by their own characteristics. However, it seems as if this moderating role has a double face: living in an economically challenged region eases the negative effects of demands on well-being, which certainly helps people feel better about their situation in the short term. Long term, however, it may undercut engagement thereby hindering the achievement of developmental tasks that would help to promote further options for better adjusted development.

When this line of research on the degree to which individuals are affected by the changes on the macro level and what this means for adjustment began, the topic of social change was almost nonexistent in psychology. The breakdown of communist rule in Eastern Europe, the gradual changes to market capitalism in countries such as China, and the democratic developments in states emerging from political oppression in countries such as South Africa, all played a role in instigating new research initiatives. More recently, the 2008/2009 worldwide economic crisis has lead to new research initiatives that utilize approaches in the tradition of Bronfenbrenner, Elder, Conger, and also the Jena model.

Stress related to globalization and other issues of social change is a major threat to mental capital and well-being, and these effects have to be seen as embedded in the entire life course, with a particular emphasis on the years marking the onset of adulthood. Spectacular evidence is provided by the consequences of rapid mass privatization on mortality in postcommunist countries. There is now evidence that among males such programs were associated with an increase in early mortality rates of about 10%. This effect was probably mediated by employment rates, and when comparing countries among those with higher social capital (participation in social organizations) the effect was reduced.

The challenges on the macro level that are behind the demands of social change are not easy to avoid or to change radically, so that, for social policy, it may be important to plan and implement interventions that support people's capabilities to deal with challenges of social change constructively. Such means have to be tailored to the type of change and to the culture within which it is found, but whatever one wants to do, interventions need to be very definite concerning clarity of expectations, certainty about implementation, and overall opportunities for peoples' striving for success. If, however, situations are blurred concerning what the new expectations resulting from social change actually are, the likelihood that people will fall back to or even 'accentuate' old behaviors rather than revert to what is actually needed given the change on the macro level (Caspi and Roberts, 2001). Whatever is the outcome on individual behavior and development can also have an effect on the macro level; the respective 'transformational mechanisms' (Hedström and Swedberg, 1996) relevant for this process have not yet been the focus of psychological research on social change.

Social and Emotional Development in the Context of the Family

Rena L Repetti, Meredith S Sears, and Sunhye Bai, University of California, Los Angeles (UCLA), Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Family relationships shape children's social and emotional behavior and understanding. When parents are warm, sensitive, and balance control with child autonomy, children learn to trust others and to regulate their negative emotions. Both discordant and supportive family interactions contribute to the development of social skills and social cognition. Repeated daily stressors at home increase physiological and emotional reactivity and promote maladaptive coping. Culture, socioeconomic status, and other aspects of the family's broader social context influence these critical dimensions of family life.

In the course of protecting, nurturing, and socializing children, families create the social and emotional fabric of their lives. Families that offer children the opportunity to balance individuality (the ability to assert oneself and a sense of self as separate from others) with connectedness (responsiveness to the needs of others) seem to foster optimal emotional and social development, at least in the subgroup of European-American middle class families that make up the vast majority of research participants (Darling and Steinberg, 1993).

Through observation of and participation in routines, habits, and rituals, children learn the expectations and norms of their cultural group, and gain a sense of belonging and membership (Grusec and Davidov, 2010). It is in the family that children first learn which behaviors and emotion expressions are, and which are *not*, socially acceptable and how to manage complex social situations. For example, children of parents who display high levels of positive affect tend to display more positive emotions among peers, while children of parents who display a lot of negative affect tend to show poorer social competence (Denham et al., 1997). Children growing up in families in which there is more frequent talk about mental states demonstrate more knowledge about emotions and greater social understanding (Dunn, 2007). Beliefs and attitudes critical to social development are also shaped by the behaviors that children observe in their families. For instance, children of substance using parents report more familiarity with substances (e.g., cigarettes, alcohol, and other drugs) and develop more favorable beliefs about their use at an earlier age (Ellis et al., 1997). Similarly, children who observe aggression during marital conflict surmise that aggression is an acceptable method of resolving disagreements, and tend to exhibit more behavioral problems themselves, such as aggression toward peers, especially if they respond to marital conflict with more negative affect or negative cognitive appraisals (Grych and Fincham, 1990; Kitzmann et al., 2003).

In short, families socialize children's behaviors, emotion expressions, beliefs, and attitudes. Family socialization takes place through interactions with genes. On the one hand, environmental inputs, such as family relationships, influence which genes are activated at different points in development. At the same time, many effects of the family environment are modified by genetically based differences between children (Repetti et al., 2011a). Our coverage of the family environment side of the equation is divided into three topic areas. First and foremost, we review the different qualities of family relationships that contribute to social and emotional development. The next two sections call attention to the importance of understanding the broader social ecology in which a family is embedded, and the diversity of different household structures.

Family Relationships

According to family systems theory, the family functions as a dynamic whole. However, most of what we know about the effects of the family on child development is based on the study of two-person dyads: the child's relationships with parents and with siblings, and the relationship between the child's parents. Evidence suggests that each dyad influences the other relationships as well as the functioning of each individual family member. Because it is through their social interactions that family members shape children's emotional and social development, our discussion is organized around these key family relationships – parent–child, sibling, and interparental. The section ends with a description of how child functioning may be shaped by certain stressful qualities of family relationships.

Parent–Child Relationships

This section describes how social and emotional behavior is socialized through interactions with parents, in particular through their provision of protection, support, warmth, affection, and sensitivity, and through their exertion of control and use of discipline. Two final subsections discuss the influence that parent psychological functioning and child behavior have on those interactions.

Parent Sensitivity and Warmth

When parents are warm, sensitive, and protective, children learn to trust adults and to regulate their feelings of distress and negative emotions. Emotion regulation, in turn, facilitates social development because negative emotions fuel antisocial behavior and interfere with the enactment of positive, prosocial behaviors; by regulating their emotional states children are better able to manage social challenges in family and peer settings. Parent caregiving, especially the protection and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23046-8

support they provide through responsiveness to signs of child distress, leads to secure or insecure attachments (Grusec and Davidov, 2007). A secure attachment is characterized by the child's receptiveness to the parent's provision of comfort, the child's tolerance of temporary separation, and his or her willingness to explore his surroundings. Trust in others and a sense of safety form the foundation for the development of social and emotional competence (Ainsworth, 1989). Parental warmth is defined as responsive, supportive, and affectionate parenting that is sensitive to the child's needs. Frequent expressions of approval and positive emotion are two indicators of parental warmth (Darling and Steinberg, 1993). Warmth generally promotes healthy social and emotional development in children, as indicated by children's understanding and regulation of their emotional states, their empathy, prosocial behavior, and level of acceptance by peers.

There are a number of ways that sensitive, warm, and protective parenting facilitates social and emotional development. The availability of a safe outlet for the expression of negative affect in a supportive context facilitates the development of children's emotion regulation skills. In addition, by observing the parent's compassionate behavior the child learns to regulate his or her own behavior and negative emotions and, in particular, learns about empathic responding to others. Empathy, in turn, motivates prosocial behavior and inhibits antisocial behavior (Grusec and Davidov, 2007). When parents are responsive to their needs and wishes, children learn how to share goals and accommodate another's needs. They become engaged in a system of mutual reciprocity, which fosters a cooperative stance in children and compliant behavior with parents, encourages the development of prosocial behavior and conscience (guilt following perceived wrongdoing), and discourages antisocial behavior (Grusec and Davidov, 2007). Dyadic synchrony, or the extent to which a parent–child dyad exhibits reciprocation of positive emotion, mutual responsiveness, and cooperation are associated with fewer behavioral problems and greater social competence in children (Harrist and Waugh, 2002).

Parents also socialize by providing direct guidance when children display distress (Morris et al., 2007). *Emotion coaching* includes labeling children's emotions, responding to children's emotion expressions with empathy and validation, and providing assistance with problem solving. Parents who are aware of their children's emotional states and view expressions of negative emotions as teaching opportunities are more likely to engage in coaching, in comparison to parents who feel discomfort when their children display distress. The children of parents who coach have better peer relationships and emotion regulation skills than those whose parents express disapproval, or are dismissive, of negative emotion.

Parent Control and Discipline

Children learn socially appropriate behavior through discussion and explanation, as well as through the parents' imposition of control and discipline, that is, through the experience of consequences for their actions. It is important to recognize that parents must enforce rules in the face of child resistance and desire for autonomy (Grusec and Davidov, 2007). Baumrind (1966) identified three iconic parent disciplinary styles. *Authoritarian* parents adhere to a strict set of guidelines about what constitutes appropriate behavior and attitudes; they emphasize obedience, not autonomy, engage in unilateral communication without opportunities for child feedback, and employ punitive measures in response to actions or attitudes that stray outside of the established guidelines. *Authoritative* parenting is characterized by high levels of emotional support, clear standards for children's behavior but bidirectional communication and autonomy-granting that allow children opportunities to influence family rules. *Permissive* parents are nonpunitive, accepting, and affirming of the child's affective states and behavior, and tend to place minimal emphasis on rules or demands. Authoritative parenting is associated with greater self-reliance in adolescent offspring, reduced rates of anxiety and depression, and less delinquent behavior, across several ethnic and socioeconomic boundaries (Steinberg et al., 1991). A mild level of parental control that preserves a child's sense of autonomy appears to be most effective in shaping behavior (Grusec and Davidov, 2010).

The effects of parenting behaviors and disciplinary styles on children's social and emotional development appear to vary depending on the child's temperament (level of fearfulness or irritability), age, and sex, as well as the nature of the child's misdeed and the emotion that the parent behavior conveys (e.g., love and concern vs hostility and rejection). In fact, the impact of parental control behaviors may depend less on the specific strategies that a parent uses and more on the child's interpretation of the parent's intent and the acceptability of that message. Sensitive and warm parenting that fosters trust increases the child's compliance, cooperation, and willingness to be guided by parent directives and to accept parental values (Grusec and Davidov, 2007; Maccoby, 2007).

Parent Psychological Functioning

A parent's psychological well being indirectly contributes to children's social and emotional development by helping to shape a family's social environment, particularly the quality of the parent–child relationship. Depression poses significant challenges for engaging in positive interactions with other family members. In mothers, depression compromises the ability to provide warm and sensitive care and is associated with the use of more negative discipline methods and with negative attribution biases regarding their children (Zahn-Waxler et al., 2002). The impact on parent–child interactions helps to account for the poor social and emotional outcomes that are often observed in children of depressed mothers; they are less skilled at regulating their negative emotions, which increases risk for developing internalizing problems (e.g., depression and anxiety), and externalizing problems (e.g., anger, hyperactivity, and impulsivity). Though paternal depression has been examined far less frequently than maternal depression, research suggests that it has a similar effect on children's risk of developing externalizing problems, but the association with internalizing problems may be weaker (Connell and Goodman, 2002). Similar to depression, parents with anxiety, schizophrenia, or antisocial personality disorders show less warmth and responsiveness toward their children. Parents with anxiety disorders also appear to experience

difficulty promoting autonomy in their children, and impose more control over their children's behaviors (Zahn-Waxler et al., 2002).

Child Contributions

Children are not passive members of their families. By triggering certain responses from others and actively seeking out particular situations and settings, children 'evoke' their own social worlds both inside and outside of the family (Grusec and Davidov, 2007). Because it is understood that parent–child interaction is transactional, with each member of the dyad continually influencing the behavior of the other, research on the parent–child relationship has shifted from a top-down perspective to one that emphasizes on the agency of the child as well as the parent (Maccoby, 2007). For instance, research involving children with disruptive behavior problems (e.g., conduct disorder) has found that the problematic behavior detracts from parents' psychological well being, as well as many aspects of parenting: responsiveness, parent–child communication, monitoring, and discipline. In fact, children's misbehaviors predicted subsequent parenting behavior more strongly than parenting predicted children's subsequent behavior (Pettit and Arsiwalla, 2008).

Sibling Relationships

In addition to parents, relationships with brothers and sisters, which are characterized by familiarity and often intense emotions, can also play an important part in social and emotional development. As Dunn (2007) has explained, it is through those familiar and intense interactions that children learn to anticipate another person's intentions and perspective, manipulate others' emotions, deceive, tease, manage conflict, and share an imaginative world in joint pretend. Siblings engage in conversations about why people behave the way that they do, and learn about mental states and feelings as causes of behavior. Sibling relationships can provide a social context for developing prosocial empathetic skills, social understanding, and emotion regulation, and they can serve as a training ground for hostile and aggressive behavior. Brothers and sisters can reinforce each other's aggression by fighting back and escalating conflict. Research indicates that conflict between siblings contributes to children's anxiety, depression, and delinquent behavior, independent of the influence of other family relationships. Developmental scholars have described a process of *sibling deidentification*, whereby siblings find different domains of interest in order to create separate and independent identities (Dunn, 2007).

The Interparental Relationship

So far we have discussed a child's own relationships with family members. However, in two-parent families, the relationship between the two parents has both direct and indirect effects on a child's social and emotional development. Coparenting refers to the way that the members of a couple support or undermine each other's parenting activities and how child care and child rearing responsibilities are apportioned. It is an important dimension of the relationship between two parents with implications for child development, particularly when there is a high level of daily hassles in the home, which appear to amplify elements of dysfunctional coparenting (Maccoby, 2007). A primary mechanism by which the interparental relationship is thought to act on child outcomes is via changes to parent–child interactions. For example, distress and conflict in the couple relationship have been found to be associated with a range of child adjustment problems; the link between couple hostility and adolescent internalizing and externalizing problems appears to be mediated by parental harshness and hostility toward the child, psychological intrusiveness and low acceptance, and parent–child conflict (Bradford et al., 2008). In the short-term, the likelihood of hostile parenting behavior and parent–child conflict rise on days when the parents engage in conflict with each other (Krishnakumar and Buehler, 2000). In the long-term, the effects of couple distress on conflicts with children have significant ramifications for children's emotional distress (i.e., anxiety and depression symptoms), a pattern that has been observed in families from European-American, Asian, and Latino backgrounds (Chung et al., 2009). Here, again, we see children playing an active role in family interactions. Negative emotional reactivity in children predicts increases in marital conflict, which in turn is predictive of children's behavior (Schermerhorn et al., 2007).

Stressful Family Relationships

A family social environment that is characterized by conflict and aggression and cold, unsupportive, or neglectful relationships poses risks for child development because it presents daily stressors to which children must repeatedly mount physiological/neuroendocrine and emotional/behavioral responses (Repetti et al., 2002). In this type of chronically stressful environment, it is particularly challenging to acquire adequate emotional and behavioral self-regulatory skills. In fact, children growing up in these 'risky families' show heightened physiological and emotional reactions to stressors, and use maladaptive coping strategies to regulate their responses. High levels of conflict at home sensitize children to anger; they react with greater distress, anger, anxiety, and fear. Periods of relief or respite from aroused emotional states may be critical to the proper regulation of emotion dynamics. However, chronic or repeated stressors, such as high levels of violence and family conflict, may not allow for sufficient recovery from heightened emotional arousal. The resulting sustained states of emotional arousal may, over time, increase reactivity, creating a sensitized stress-responsive system. Moreover, children from families characterized by conflict, overt anger, hostility, and abuse are more likely to maintain a heightened state of vigilance for signs of anger and are also more likely to respond with distress, anger, and aggression to incidents that involve anger, discord, and tension. Compared to other children, they appear to be hyperprepared for threats and hyperresponsive to those threats, which may contribute to increased reactivity (Repetti et al., 2011b).

Family members' negative mood and physiology can compound the impact that risky families have on child development. Through processes of emotion transmission

(short-term links between one member's momentary negative mood and another member's concurrent or subsequent emotional experience) and physiological coregulation (e.g., linkages between family members' day-to-day fluctuations in levels of the hormone, cortisol, which is associated with stress), the mood and physiology of one family member can be affected by the mood and physiology of another family member (Repetti et al., 2011b).

The Social Ecology of the Family

We shift here from a focus on relationships to factors that shape family life. According to Bronfenbrenner's (1989) social ecological model, the influence that families have on child development can only be understood by taking into account the broader social milieu in which families are embedded. Three dimensions of that larger world and their influence on the family social context are discussed next: culture, socioeconomic status (SES), and stressors from both inside and outside the home.

Culture

Child-rearing practices and patterns of family interaction vary in different cultures. For example, ethnographic studies show that sibling caregiving is much more widespread and significant in many cultures than it is in the United States. In many non-Western communities, these sibling experiences play an important role in socialization for parenthood (Dunn, 2007). Researchers have also identified (1) differences in the parenting styles typically exhibited in different cultures, as well as (2) interactions between parenting behaviors and culture in child social and emotional outcomes. With respect to the first point, middle class European-American families – that is, parents in an individualistic culture that prizes autonomy – most often exhibit authoritative parenting styles, whereas parents from collectivist cultures (e.g., Indian and Egyptian) more often exhibit authoritarian parenting (Rudy and Grusec, 2006). Authoritarian parenting also predicts more fearful, compliant behavior among European-American girls but more assertive behavior among African-American girls (Darling and Steinberg, 1993).

Studies of differences between authoritarian and authoritative parents in collectivist and individualist cultures suggest that authoritarianism has detrimental effects on child outcomes only in individualist cultures, through the mechanism of higher maternal negative emotion and cognition (Rudy and Grusec, 2006). One possible explanation for these findings is that Baumrind's parenting styles (1966) do not entirely capture the 'how' of parent–child interactions: parents may be more obedience-oriented, but this does not necessarily determine whether discipline is delivered with harshness or nurturance. Typical Chinese parenting, for instance, has been described as authoritarian 'training' delivered with involvement, care, and concern for the child's welfare (Chao, 1994), which leads to more positive child outcomes than the authoritarian parenting exhibited in European-American families. However, there is research to suggest that even when examining child outcomes in individualist vs collectivist cultures, authoritative parenting is still associated with more positive social and emotional outcomes than authoritarian or permissive parenting (Sorkhabi, 2005). This is certainly a topic that requires more empirical investigation.

Socioeconomic Status

SES is an important dimension of a family's social ecology. Parents' expectations, values, styles, and behaviors toward their children vary with the family's SES (Hoff et al., 2002). In general, higher-SES parents tend to place a higher value on independence and self-direction for their children. There are corresponding differences in parenting styles and behaviors: lower-SES parents tend to show more authoritarian and permissive styles of parenting, whereas higher-SES parents exhibit the authoritative style more frequently (Kohn, 1969). Overall, the latter group emphasizes democracy and child-centered styles of parenting, whereas lower-SES groups tend to practice more parent-centered styles. As such, lower-SES parents promote less autonomy and cooperation with their children. In addition to these differences in parenting style, lower-SES parents are less able to monitor their children or be as involved with their children's homework and extracurricular activities, in comparison to higher-SES parents. These differences may be in part attributable to extrafamilial stressors that are more common in lower-SES families, such as higher work stress, lack of neighborhood resources, and financial strains.

Economic resources determine what type of nutrition and health care children receive, the quality of a family's housing, as well as the child's exposure to toxins, such as air pollution, and community violence. Low-income families are less able to provide children with high quality educational opportunities and enriching activities, such as books, music, and art, or with access to museums, clubs, and sports teams. The stress of economic hardship and job loss undermine parents' abilities to respond in nurturant ways to their children. Children growing up in impoverished families are more likely to suffer physical abuse, verbal abuse, and neglect, to experience family instability, and to be exposed to poor socialization practices at home, including parenting that is more coercive and less authoritative, warm, and engaged (Patterson and Hastings, 2007; Repetti et al., 2002).

The Impact of Chronic and Daily Stressors on Family Life

Chronic life stress – whether due to the demands of economic strain, marital problems, difficulties at work, or health problems – influences how parents interact with children and their attitudes about parenting. In general, more stressed parents tend to display less positive and more negative affect, less responsiveness, and less consistent discipline toward their children. Parents under chronic stress tend to hold higher and less developmentally appropriate expectations for their children, and view their children as displaying more anger (Crnic and Low, 2002; Morrison Gutman et al., 2005). This observation (that parents who report high levels of chronic stress also exhibit more psychological distress and depressive symptoms) explains how stress is linked to parenting behaviors.

On a day-to-day basis, parenting behavior can change according to events that occur outside the parent–child relationship. Daily stressors such as feelings of being overloaded at

work, interpersonal difficulties at work, and disruptions in the interparental relationship (e.g., marital conflict) affect how parents interact with their children. For example, when parents experience stressful days at work, they are more likely to engage in either social withdrawal – defined as reductions in expressions of emotion, such as affection, and social engagement – or in conflictual or angry interactions with spouses and with children (Repetti et al., 2009). This process is known as 'spillover' because stress in one context (in this case, work) is 'spilling over' into another context (in this case, family interactions; Repetti, 1987).

Family Structure and Diversity

Finally, we note that many children today are reared by single parents, never-married couples, lesbian and gay couples, grandparents, step-parents, adoptive parents or, thanks to advances in alternative reproductive technologies, such as donor insemination and egg donation, by parents to whom they have no genetic tie. Research examining these different family forms indicates that the family resources, social processes, and relationships covered above are much more important for children's social and emotional development than is the family's structure (Patterson and Hastings, 2007). However, economic resources are unevenly distributed across different family structures. Two parents, compared to one, have access to greater economic resources, and have more extensive social support networks; plus two parents can provide support and encouragement for one another.

Increased parenting stress, less access to resources and social support, and the lower quality of parenting that is sometimes found in single-parent families are risk factors for difficulties in children's socioemotional development. Single mothers report more dysfunctional interactions with their children, including more severe disputes, less enjoyment of motherhood, lower overall quality of parenting and more parenting stress, than do mothers with partners (whether opposite or same-sex; Patterson and Hastings, 2007).

Although the mechanisms are not clear, the offspring of heterosexual parents who are married show better adjustment than the offspring of unmarried heterosexual parents. Children with lesbian or gay parents develop in much the same ways as other children. No differences have been observed in their social, emotional, or sexual development, and the predictors of development in children reared by heterosexual and gay parents are the same: child rearing behaviors, parenting style, family management. In general, the genetic relatedness of parent and child and parental sexual orientation do not seem to be important for children's social and emotional development (Patterson and Hastings, 2007).

Conclusions

A tremendous amount of social and emotional development takes place in the context of family relationships. The family provides the social partners and experiences through which children learn about trust, intimacy, empathy, control, and the complex rules of social interaction; the role models for behavior and emotion expression; the 'culture brokers' who introduce children to ways of acting and knowing; and the daily challenges and stressors to which children must learn to respond and cope. Those experiences, in turn, reflect and are shaped by the larger social world in which the family exists. Although our discussion has focused on childhood, the family's influence begins in infancy, and continues through adulthood, when relationships with a new family created through marriage and parenthood, as well as enduring relationships with the family of origin, have profound effects on emotional and social well being (Repetti et al., 2011a).

Social Beliefs and Attitudes: Personality and the Isms

Jeremy Burrus, ACT, Iowa City, IA, USA

Abstract

Social attitudes and beliefs can have a powerful influence on how one interprets, and respond to, everyday events. Employing a factor analytic approach, Saucier (2000, 2013) has recently developed a taxonomy of social attitudes and beliefs which contains five dimensions. He labeled these dimensions 'isms' because words describing these attitudes and beliefs tend to end in 'ism' (e.g., fundamentalism, relativism, and materialism). The five dimensions of isms are: tradition-oriented religiousness, unmitigated self-interest, communal rationalism, subjective spirituality, and inequality-aversion. In this article we briefly discuss beliefs and attitudes more generally before discussing isms in detail. We then discuss the relationship of Big Five personality dimensions to isms and additional correlates of isms before providing a few areas for future research directions. The article concludes by making an argument that isms are a potentially very important, but highly under-researched, aspect of human individual differences.

Each of us adheres to a set of beliefs and attitudes that, at least in theory, guide the way we interpret events and respond to them. We are consciously aware of most of these beliefs. For instance, when I get into my car in the morning to go to work, I believe that turning the key will start the engine. And so, faithfully, every morning I turn the key, expecting my car to start. Almost invariably, it does. Only when the engine does not start do I start to question the veracity of this belief. Other beliefs are held more implicitly. For example, while some implicitly believe that each of us is born with a fixed amount of intelligence (an 'entity' theory), others believe that intelligence is malleable and can be increased with practice (an 'incremental' theory; Dweck et al., 1995). As another example, people have a tendency to believe that something is more likely to be true the more often they have heard it (e.g., Allport and Lepkin, 1945). At times, these beliefs can have an evaluative quality. I can believe that my soul will enter the afterlife after I die, and I can also believe that it is *good* for my soul to enter the afterlife after I die. Typically, the evaluative components of beliefs are referred to as 'attitudes.'

A particular set of beliefs and attitudes, "… whose referents have shared general societal relevance to many people in religious, economic, political, educational, ethnic, and other social areas" (Kerlinger, 1972: p. 614, as cited in Saucier, 2000) can be referred to as 'social attitudes and beliefs.' For example, people who believe in egalitarianism believe that all people should be treated equally, regardless of their status in the social hierarchy. As such, they will tend to treat all people in a similar fashion. In everyday conversation, we use a range of words to describe such different belief systems, that could be used to describe social (e.g., egalitarianism and ethnocentrism), political (e.g., liberalism and conservatism), and religious (e.g., spiritualism and religionism) attitudes or beliefs, all of which might affect the way we behave. Note that each of the example social attitude or belief ends in 'ism.' Thus, these terms were labeled 'isms' by Saucier (2000).

In the following section, we delve deeper into the origin and structure of beliefs and attitudes. Next, we provide more detail specifically on social attitudes and beliefs, focusing on Saucier's isms dimensions. We then discuss several issues surrounding isms, including their relation to Big Five personality dimensions, their relationship to other constructs, and future directions for research involving isms. Although some empirical findings are discussed, because isms are a relatively understudied construct, much of this discussion relies heavily on theory.

Beliefs

A belief is how sure one is that knowledge acquired (e.g., the Earth revolves around the sun) or a subjective experience (e.g., last night's party was the most fun night of my life) is true (Wyer and Albarracin, 2005). Beliefs can vary in terms of strength, such that the surer one is that a proposition is true, the stronger the belief. They can refer to objects or events from the past (e.g., Facebook was founded on 4 February 2004), the present (e.g., my wife is 5′ 9″), or the future (e.g., all cars will be driverless in 15 years). Beliefs about the future can also be thought of as 'expectations' (Wyer and Albarracin, 2005).

As stated briefly above, beliefs can also be held explicitly or implicitly. On the one hand, explicitly held beliefs are those which one is aware of holding. For example, I have a very strong explicit belief that I had scrambled eggs and coffee for breakfast this morning. On the other hand, unless brought to conscious awareness, one is generally unaware of holding implicit beliefs. Oftentimes, these beliefs consist of basic assumptions regarding the workings of the mind and the world in general, and are sometimes referred to as implicit, or naive, theories (e.g., Dweck et al., 1995; Schwarz, 2004; Wyer and Albarracin, 2005). The entity versus incremental theories of intelligence example from above is one example of an implicit theory. Others include the naive theory that written material that is easier to process (e.g., is written clearly rather than blurrily) has been seen before (e.g., Schwarz, 2004), and that behavior has occurred more frequently if examples of it can be easily brought to mind (Schwarz et al., 1991). An important point in distinguishing explicit versus implicit beliefs is that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25082-4

implicit beliefs can influence our judgment, and subsequent behavior, without our awareness.

Beliefs can be based in cognition or motivation. Clearly many of the examples of beliefs discussed above are cognitive in nature. They refer to the probability that knowledge acquired through experience about oneself or others, events, places, or objects, is true or correct. People may also hold beliefs because they are motivated to do so. Although people might hold a variety of motivations, a few basic ones have been identified in the psychological literature. For example, people strive to interact meaningfully with other individuals ('communion striving'), to have influence over others ('status striving'), to have control over their lives ('autonomy striving'), and to feel competent ('achievement striving'; see Barrick et al., 2013 for a review). Additionally, people have the need to feel like the world is fair and just (Lerner and Miller, 1978), and also the need to reconcile thoughts of their own impending deaths (Greenberg et al., 1986). Individuals vary on their level of each of these needs; one might have a very low need for communion striving but a high need for achievement striving, whereas another person might demonstrate the opposite profile. Beliefs can be generated that can help ease one's concerns about each of these motivations. For example, the belief, "Even though I have few friends, the friends I do have are very close to me." might be generated to help one feel he or she is achieving progress toward fulfilling the communion striving need. Additionally, the belief, "People have souls that are separate from their physical bodies" might be generated to help ease one's fear of death.

Attitudes

An attitude is an evaluation of a person, object, or event (Eagly and Chaiken, 1993). They consist of an experiential and an instrumental component (Ajzen, 2006). The experiential component represents the valence of the entity and can be measured with scales ranging from *good–bad*, to *pleasant–unpleasant*, to *enjoyable–unenjoyable*. The instrumental component represents the utility of an entity and can be measured with scales ranging from *useful–useless*, to *beneficial–harmful*, and to *valuable–worthless*. Thus, it can be said that I have a positive attitude toward math if I enjoy the experience of doing math, and/or if I feel that math is useful and valuable (e.g., Lipnevich et al., 2011).

Although the relationship of beliefs to attitudes is not necessarily agreed upon (Wyer and Albarracin, 2005), one prominent theory of attitudes states that attitudes develop from beliefs (Ajzen, 1991). That is, beliefs about a person, object, or event become linked to a positive or negative attribute to form an attitude. Because I am pretty sure that I was born, I have a very strong belief that I indeed have a birthday. My attitude toward my birthday, however, may change with age. When I am young, I associate my birthday with positive features (parties and presents), and so I have a positive attitude toward my birthday. Later in life, however, I may begin to associate my birthday with negative features (getting older and thus closer to death), and my attitude toward my birthday may turn negative. These positive or negative associations can come from personal experience or from witnessing (or learning about) others' experiences (e.g., "Social Learning Theory," Bandura, 1977).

If attitudes are truly derived from beliefs, it follows that they, too, have both cognitive and motivational bases. We can develop an attitude because we know (or think we know) something, or we can develop an attitude because we want (or need) to believe something. Similarly, attitudes can be explicitly and implicitly held (Nosek, 2007). As with beliefs, an explicit attitude is one that is aware of holding and can consciously report on. In contrast, one is not always aware of holding an implicit attitude and thus he or she cannot consciously report on them. In fact, they are usually activated automatically. Typically, they are measured with the Implicit Association Test (IAT), which measures the strength of associations between two sets of concepts (e.g., good vs bad; black vs white). Explicit attitudes often agree with implicit attitudes (Nosek, 2007) but sometimes diverge. For example, people often explicitly claim no racial favoritism, although results from the IAT find that they implicitly favor whites to blacks (Nosek et al., 2002).

Social Beliefs and Attitudes: Isms

As briefly described above, social attitudes and beliefs have been coined "Isms" by Saucier (2000). Prior to the year 2000, several social attitudes and beliefs had been identified in the research literature (e.g., Adorno et al., 1950); however, no attempt was made to create a taxonomy of such attitudes and beliefs until Saucier's seminal work.

In an attempt to find a simplified structure within such a wide range of attitudes and beliefs, Saucier (2000) factor-analyzed 266 isms using a population of college students. He found four dimensions of isms, initially labeling them with Greek letters to avoid using misleading terms in categorizing such broad factors. He later felt more comfortable in providing more conventional labels to these dimensions. Saucier (2000) provides a detailed description of the first four dimensions. His descriptions are summarized below and additional examples and definitions are included in **Table 1**.

'Alpha,' or 'tradition-oriented religiousness,' is described as the degree to which an individual reveres religious authority and believes in, and supports, conventional and traditional forms of religion. Cultural traditions are important for those who score high on alphaisms. This value may result in many behavioral manifestations, including a willingness to behave aggressively in the name of traditional sources of authority. It would follow, for example, that many of those who volunteered to participate in the Crusades in the late Middle Ages in the name of the Catholic Church would have scored high on alpha. Taking an example from more recent events, we would hypothesize that the political unrest in the Middle East, and the associated aggressive actions taken, is highly motivated by alphaisms. An example item used to measure alpha is, "Religion should play the most important role in civil affairs."

'Beta,' or 'unmitigated self-interest,' measures the degree to which someone justifies different forms of self-interest, such as materialism or forms of physical pleasure. According to Saucier (2000), it concerns attitudes and beliefs about one's immediate environment. While many alphaisms focus on the past,

Table 1 Example isms and their definitions

Alpha (tradition-oriented religiousness)	
Calvinism	God is all-powerful, and those whom God chooses will be saved by God's grace alone.
Secularism	Religious considerations should be excluded from civil affairs and public education.
Triumphalism	Moral laws are fixed, absolute, and the same everywhere.
Beta (unmitigated self-interest)	
Solipsism	The self is the only thing that can be known and verified.
Materialism	Physical well-being and worldly possessions are the greatest good and highest value in life.
Ethnocentrism	I believe in the superiority of my own ethnic group.
Gamma (communal rationalism)	
Nationalism	I am devoted to one particular nation.
Hedonism	Behavior is motivated by the desire for pleasure and the avoidance of pain.
Fundamentalism	I adhere firmly to fundamental and basic principles.
Delta (subjective spirituality)	
Animism	There are spiritual beings separate, or separable, from bodies.
Anthropomorphism	Many nonhuman things have human motivation and human characteristics.
Pragmatism	I adhere to and am dedicated to the facts.
Epsilon (inequality-aversion)	
Classism	I prefer people of a certain social or economic class.
Communalism	I believe in communal (group or community) ownership of goods and property.
Anarchism	All forms of government are oppressive and undesirable and should be abolished.

Reproduced from Saucier, G., 2000. Isms and the structure of social attitudes. Journal of Personality and Social Psychology 78, 366–385; Saucier, G., 2013. Isms dimensions: toward a more comprehensive and integrative model of belief-system components. Journal of Personality and Social Psychology 104, 921–939.

betaisms tend to be present focused. We hypothesize that an individual high on betaisms would be more likely to sacrifice potential future gains for present ones than an individual low on betaisms. As such, for example, we would conjecture that most environmental activitists would score low on betaisms. One example item is, "The pleasures of the senses are the highest good."

'Gamma,' or 'communal rationalism,' stresses the support of a nation and a common institution which guarantees individual freedom and which emphasizes the use of reason. This dimension covers isms such as patriotism, humanism, and functionalism. We believe that the prototypical coach of a team sport provides an apt example of a person high on gamma. A quick scan of the gamma examples in **Table 1** makes this clear. 'Nationalism' (I am devoted to one particular nation) can be retranslated to 'teamism' (I am devoted to one particular team). 'Hedonism' (Behavior is motivated by the desire for pleasure and the avoidance of pain) is displayed in coaches who motivate players by inducing pain to punish player mistakes (e.g., yelling at them and making them run extra laps). Finally, 'fundamentalism' (I adhere firmly to fundamental and basic principles) is clearly a part of coaching, as one important job of the coach is to teach a sport's basic fundamentals and principles. An example gamma item is, "I believe in government by law with the consent of those people governed."

'Delta,' or 'subjective spirituality,' is the degree to which a person values subjective spiritual or 'paranormal' experiences. Though some psychologists tend to group religion (or alphaisms) and spirituality (deltaisms) into one factor, evidence shows these are two distinct factors (Saucier, 2000, 2013; Saucier and Skrzypińska, 2006). Religious beliefs place emphasis on the opinions of an organized group of people, while spiritual beliefs are formed based on subjective experiences and individual feelings. Saucier (2000) implies that delta has roots in Indian Hinduism, and, in American tradition, Transcendentalism. An important aspect of delta is the belief that divinity is not exclusive to humans; nature also has divine aspect. An example delta item is, "Enlightenment is gained through meditation, self-contemplation, and intuition."

Later, Saucier (2013) again factor-analyzed a large collection of isms, but this time with a wider community sample. He replicated the four factors of alpha, beta, gamma, and delta. However, there was also evidence of a fifth factor, 'epsilon,' or 'inequality-aversion,' relating to egalitarianism. "One pole of the dimension is anchored by item clusters endorsing communal ownership, social welfare programs, and a socialist society; the other pole involves views supportive of domination of one class, group, or nation over others (e.g., elitism, chauvinism, and jingoism). This dimension is concerned foremost with attitudes toward inequalities within one's own society, but this extends secondarily to inequalities between societies" (Saucier, 2013: p. 931). An example item is, "Free market capitalism leads to gross inequalities in income and wealth, which is a great social evil." Thus, the current Survey of Dictionary-based Isms (SDI), developed by Saucier, contains items that measure all five of the dimensions.

It should be clear from the examples provided that isms are indeed forms of beliefs (e.g., Solipsism: "The self is the only thing that can be known and verified.") and attitudes (e.g., Materialism: "Physical well-being and worldly possessions are the greatest good and highest value in life."). As such, it follows that if beliefs and attitudes can be held both explicitly and implicitly, then so should isms. We posit that, if the explicit/implicit distinction is thought of as a continuum, most isms would fall closer to the implicit side of the pole. It seems clear that many isms are influenced by, or are indeed products of; ideas imbued by one's culture that drive one's view of the world.

One definition states that culture has three components that are learned and shared by a group of people: "(1) The *things* people make and use (called artifacts), (2) the ways people *behave* (including language), and (3) the *ideas* people have" (e.g., Caligiuri et al., 2011: p. 2). These components are thought to be relatively stable in nature, although they can change depending on circumstances (Caligiuri et al., 2011). Culture is often explained using the iceberg metaphor (e.g., Herman, 1970), such that most of culture's influence in everyday life is unseen or 'below the surface of the ocean.' The part that can be seen or is above the surface includes the norms, artifacts, and behaviors of specific cultures. Just below the surface are the values and interests held by specific cultures. Finally, deeper below the surface still are the assumptions held by specific cultures. These 'below the surface' aspects of culture appear to be synonymous with isms. It is thought that cultural assumptions influence values and interests, which then influence norms,

artifacts, and behaviors. Isms may represent some combination of culturally influenced assumptions, values, and interests.

The likely relation of isms to cultural values and assumptions calls to mind other taxonomies of cultural values. For instance, Hofstede (1983) has identified several dimensions upon which cultures vary. These include: 'power distance' (acceptance of unequal power); 'uncertainty avoidance' (tolerance for ambiguity); 'individualism versus collectivism' (the degree that people are oriented toward groups); and 'masculinity' (the degree to which men and women's values differ in a society). Another prominent theory, Schwartz's (1992) cultural values, identifies several values that can be organized into two factors: 'organization versus change' and 'self-enhancement versus self-transcendence.' To the best of our knowledge, the relation of isms to Hofstede's dimensions has not been investigated. Saucier (2013) did investigate the relation of isms to Schwartz's dimensions and found that three of the isms dimensions fell within the Schwartz two-dimensional structure, with subjective spirituality and communal relationism falling outside of the structure.

One possible way that isms differ from the beliefs and attitudes discussed above is that, whereas beliefs and attitudes in general vary as to the extent to which they are cognitively or motivationally determined, isms seem to be primarily motivational in nature. That is, each of the isms provided in the examples in this article (see Saucier, 2000, 2013 for a complete list) can be said to speak to one of the fundamental motives described above. For example, to conjecture from the examples listed in **Table 1**:

- *Communalism* (I believe in communal (group or community) ownership of goods and property) relates to communion striving
- *Classism* (I prefer people of a certain social or economic class) relates to status striving
- *Solipsism* (the self is the only thing that can be known and verified) relates to autonomy striving
- *Materialism* (physical well-being and worldly possessions are the greatest good and highest value in life) relates to achievement striving
- *Triumphalism* (moral laws are fixed, absolute, and the same everywhere) relates to the need to feel the world is fair and just
- *Animism* (there are spiritual beings separate, or separable, from bodies) relates to the need to reconcile thoughts of one's own death

If the isms are indeed related to one's basic motivations and needs, this suggests that manipulating these motivations (e.g., making thoughts of death more accessible) should lead to a change in one's endorsement of corresponding isms. Although we do not know of any research that speaks directly to this issue, some naturalistic research does speak indirectly. For example, in the days immediately following the terrorist attacks of 9/11 (a clear example of increasing the salience of one's death) 74–82% of Americans showed their patriotism by displaying the American flag on their home, car, or person (Morgan et al., 2011). This percentage had decreased to 56% by 2003.

Although we speculate that one's endorsement of isms can be manipulated, and thus are malleable, isms are typically thought of as relatively stable individual differences. This may come as a surprise to some given the large literature in social psychology that documents techniques for persuasion and attitude change (e.g., Cialdini, 1993). However, certain types of attitudes have shown considerable stability. Such is the case with vocational interests; attitudes about activities involving goal-related behaviors (Rounds and Su, 2014). Meta-analysis has found that interests stabilize as early as age 12, and remain stable at least through middle adulthood (Low et al., 2005). In fact, they appear to be more stable than personality. One commonality we see between isms and vocational interests are their high relevance to the self. It is likely that highly self-relevant attitudes are more accessible (easier to bring to mind) than less self-relevant attitudes (e.g., Fazio and Olson, 2007). As such, they influence one's interpretation of daily life events and, as they do so, increase in strength over time. The fact that isms have been identified by Saucier as individual differences, and the likelihood that they are relatively stable, may suggest to some that isms might simply be another way to label the Big Five personality traits. This is discussed briefly in the following section.

Isms and Personality

Many have questioned the ways in which personality and belief systems overlap; some believed that various beliefs could be just another dimension of personality (Adorno et al., 1950; Homer and Kahle, 1988). Saucier (2013) found that each of the five ism dimensions significantly correlated with at least one of the Big Five factors, yet they did not correlate higher than $r = 0.25$. This suggests that the isms dimensions do have important associations with the Big Five, but are actually unique from these personality factors. For example, people who were less conscientious were more likely to endorse subjective spiritualism (however, there was no significant correlation between conscientiousness and endorsing traditional religions). People who were more agreeable were more likely to endorse inequality-aversion and be more egalitarian, as one might expect. Openness was found to be negatively correlated with unmitigated self-interest, while people who were less emotionally stable were more likely to endorse traditional religions. Saucier (2013) also examined change in personality characteristics across the span of 10 years and found that unmitigated self-interest was correlated with a negative change in agreeableness, conscientiousness, emotional stability, and openness.

Isms, thus, represent one alternate conceptualization of personality that focuses on individual differences in social attitudes and beliefs. Importantly, the magnitude of correlations of isms and the Big Five personality factors suggests that they do not completely overlap with the Big Five. This suggests that isms might act as an important complement to the Big Five for both illuminating the nature of individual differences and predicting important outcomes.

Other Correlates of Isms

The relative paucity of research on isms means that very little work has been conducted investigating isms's correlates.

Recently, however, Saucier (2013) has examined the relation of isms to previously used measures of social attitudes and beliefs, political preference, and subjective well-being (SWB). He found that several isms correlated significantly with previous measures of social attitudes and beliefs. To provide few examples of correlations that exceeded 0.20, tradition-oriented religiousness and inequality-aversion correlated with right-wing authoritarianism (social conservatism) at 0.76 and −0.29 respectively, and, unmitigated self-interest and inequality-aversion correlated with social dominance orientation (a preference for hierarchy) at 0.22 and −0.54, respectively. Thus, it could be argued that tradition-oriented religiousness and inequality-aversion overlap to such an extent with previously identified constructs so as to be redundant. This is especially the case for tradition-oriented religiousness.

Interestingly, only one ism was found to be significantly correlated with measures of subjective well-being, communal rationalism, which suggests that people who believe in the importance of a fair and just government are also happier. The relationship was weak, however, ($r = 0.13$). Given the oft-replicated finding that those who participate in religious activities tend to have higher SWB (Diener et al., 1999), it is surprising that people who endorsed traditional religious or spiritual beliefs were not found to be significantly happier. Finally, isms were related to political preference, with republicans more likely to be high on tradition-oriented religiousness, and democrats more likely to be high on communal relationism, subjective spirituality, and inequality-aversion.

Future Directions

There are numerous avenues for future research on isms. One important area will be to investigate the development and temporal stability of isms. Presumably, given the discussion of above, one strong influence of ism development is one's culture. However, other influences likely come into play. One obvious influence should be religious upbringing. Others include parental attitudes and parenting style, sociopolitical events that occur during one's formative years, formal and informal educational experiences, and a host of idiosyncratic personal experiences. Furthermore, some social attitudes have been shown to have a genetic component (e.g., Waller et al., 1990), and so, too, could isms.

As is the case with vocational interests, we suspect that isms are relatively stable throughout the lifespan. However, despite prior belief to the contrary, individual differences such as personality have been shown to change throughout the lifespan (e.g., Roberts et al., 2006). As we posited above, one possible mechanism for ism change over the lifespan would be to threaten one's basic needs. For instance, major sociopolitical, or personal life, events that threaten one's belief that the world is fair and just could lead to shifts in one's level of tradition-oriented religiousness.

Another important area for future research will be to replicate the structure of isms across several cultures. To the best of our knowledge, the only attempt at a cross-cultural replication was Krauss's (2006) replication in Romania. In this study, Krauss roughly replicated the first four isms factors. It will be important, however, to replicate the structure in non-European cultures, such as the cultures of Asia, Africa, and Latin America. It is our belief that nearly any pattern of results would be interesting. Replication across all, or most, cultures might suggest a common human evolution of social attitudes and beliefs that are somehow related to the survival of the species. By contrast, distinct isms patterns across cultures would provide important information about the structure of cultural differences.

A final area for future research will be to predict important school and work outcomes with isms. Meta-analysis has found that attitudes predict a wide range of behaviors (Kraus, 1995), and individual difference measures predict important outcomes both at school (e.g., Poropat, 2009) and at work (e.g., Judge et al., 2013). Isms should be no different. Numerous hypotheses can be put forth. Some examples include:

- Tradition-oriented religiousness is negatively related to creativity
- Unmitigated self-interest is negatively related to teamwork
- Communal relationism is positively related to leadership
- Subjective spirituality is positively related to coping skills (this hypothesis is less clear than the others)
- Inequality-aversion is positively related to organizational citizenship behaviors (positive behaviors such as helping coworkers, being cooperative, and putting forth extra effort to get the job done; Borman and Motowidlo, 1993).
